GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index is \$75.00, Domestic and \$90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: **CARCINOGENESIS ABSTRACTS**, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

REVIEW

79-0001 Decision Point Approach to Carcinogen Testing. (Eng) Weisburger, J. H. (American Health Foundation, Valhalla, NY, 10595); Williams, G. M. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 45-52; 1978.

A standardized approach to assessing potential human cancer risk, the Decision Point Approach, consists of a sequential series of tests and a final evaluation. The first area of concentration should be structure-activity correlations. Studies of compounds such as azo dyes and arylamines reveal that data on the structure of the suspect chemical as well as potential metabolites can lead to success in predicting the carcinogenicity of untested structurally related compounds. A series of rapid in vitro tests (applied as a battery) should follow. They comprise mutagenicity, DNA repair, and cell transformation tests. The next steps are a series of limited bioassays in rodents and conventional chronic toxicity and carcinogenicity tests. The decision as to whether a material is a cancer risk is made after a two-stage review. First, a body of cancer experts would review the data to decide if a carcinogenic risk may be present; a negative decision would solve the question. A positive vote would be passed on to a board comprised of many representatives of society, who would weigh risks vs benefits and make a recommendation as to the use of the material. (62 refs)

79-0002 Models for Carcinogenic Risk Assessment (6 Letters to Editor). (Eng) Brown, C. C. (NCI, Bethesda, MD, 20014); Fears, T. R.; Gail, M. H.; Schneiderman, M. A.; Tarone, R. E.; Mantel, N.; McGaughey, C.; Crump, K. S.; Neyman, J.; Scherer, E.; Emmelot, P.; Cornfield, J. *Science* 202(4372): 1105-1109; 1978.

Five critiques and a rebuttal by the author are presented to a report of a simple kinetic model for carcinogenesis that could lead to a threshold. This threshold depends on the existence of at least one irreversible, completely protective reaction in carcinogenesis. Inadequacies in the derivation of the model are pointed out, and concern is expressed over the assessment of low-exposure carcinogenic risk. Deactivation of a toxic substance will take time to reach equilibrium and, under the assumption of proportionality between dose and the probability of a carcinogenic response, if any activated complex ever reaches the target site, a threshold will not exist. The model also unrealistically assumes that there is a single exposure in environmental carcinogenesis. In another cri-

tique, it is stated that the model does not account for initiation and promotion and thus has limited value when the possible combinations of initiating agents, promoting agents, and time frames are considered. The threshold model is unstable, since a slight perturbation of the model in the direction of realism does away with the threshold and leads to low-dose linearity. The model does not recognize that the response to a carcinogen depends on the rate of exposure and it does not allow for the phenomenon of synergism. According to another critique, the threshold holds for the special case of a steady-state model in which the deactivation reaction is irreversible and will not hold when the time course of the reaction is taken into account. The author answers that the model is not dependent on the existence of a threshold. (25 refs)

79-0003 Cancer Epidemiology--Part V. (Eng) Harberg, J. (Wisconsin Clinical Cancer Center, 1900 University Ave., Madison, WI, 53705); Buchanan-Davidson, D. *J. Wis Med J* 77(11): 26-27; 1978.

Risk factors and incidence and mortality patterns associated with stomach and colorectal cancer are presented from a review of the literature. Substances in the diet may be significant to both cancer types. (31 refs)

79-0004 Approaches to the Prediction of Carcinogenic Effects Using Quantitative Structure-Activity Relationships (QSAR). (Eng) Chu, K. C. (NCI, Bethesda, MD, 20014). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 95-97; 1978.

In attempts to analyze the metabolic activation of chemicals, quantum mechanical (computer) studies are using models to predict the formation of ultimate carcinogens and also the criteria for their formation. The predictions are based on quantitative structure-activity relationships that are used in "fundamental" approaches to the mechanisms of carcinogenesis and in "empirical" approaches involving the analysis of existing data relating substructure to the biological response of previously tested compounds. Specifically, the fundamental approach examines how a compound might react with macromolecules (free radical, SN1, or SN2 type reactions), whereas the empirical approach examines the sum of parameters such as resonance, field and steric properties, and

lipophilic and conformational effects. In a general scheme of chemical carcinogenesis, a compound enters the body through the mouth, nose, or skin, and is absorbed into organs capable of metabolic activation. The chemical may then be eliminated, detoxified to inactive metabolites, or activated into a procarcinogen. The latter may, in turn, be activated to any ultimate carcinogen capable of binding covalently to macromolecules. If such conjugates affect macromolecule replication or its effect is not "repaired" by the cell, cancer induction will occur. (15 refs)

- 79-0005 Hansch Analysis and the Use of Partition Coefficients.** (Eng) Leo, A. J. (Pomona Coll., Ontario, CA, 91511). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 55-62; 1978.

Hansch analysis is an extension of the Hammett equation of physical organic chemistry applied to bio- and medicinal chemistry. Drug transport is one of the most important phenomena of biosystems. Used in a linear fashion, the hydrophobicity parameter (partition coefficient) could not account for the fact that in some transport phenomena, an optimal hydrophobicity is apparent. In Hansch analysis, this might be explained in a kinetic model in which a series of lipid/aqueous compartments has to be traversed by the drug, with partitioning occurring between each phase boundary. Computer simulation readily shows that the rate at which the drug appears in the final compartment is a parabolic function of the partition coefficient. The hydrophobicity parameter should play an important role in assessing the danger of carcinogens to humans. The octanol-water partition coefficient can be a useful parameter to model the adsorption of chemicals to soil and their absorption into aerosols. Furthermore, partition coefficients have been conclusively shown to be an excellent parameter for modeling bioaccumulation. Hydrophobicity must always be taken into account in the design of experimental tests for carcinogenicity, as administration vehicles may affect the sensitivity of a test or the locus of primary tumors. (15 refs)

- 79-0006 Session II. Carcinogen Screening: Obstacles and Options. In Vitro Testing of Environmental Mutagens/Carcinogens.** (Eng) Ames, B. N. (Univ. California, Berkeley, CA, 94720). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 27-33; 1978.

The development, accuracy, and recent applications of the Ames *Salmonella* mutagenesis test are discussed. Chemicals tested for mutagenicity and carcinogenicity have included flame retardants in children's pajamas, pesticides, vinyl chloride, and dibromo compounds in citrus-flavored soft drinks. (9 refs)

- 79-0007 In Vivo Testing of Carcinogens.** (Eng) Griesemer, R. A. (NCI, Bethesda, MD, 20014). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 34-37; 1978.

Design considerations in in vivo carcinogen testing and obstacles to properly carrying out such tests are reviewed. In the approach used by the National Cancer Institute to identify chemical carcinogens, two species of animals of both sexes are exposed to the test chemical using the highest doses the animals can tolerate. After 2 yr, survivors are killed and the tumors produced compared with spontaneously occurring tumors in controls. The purity of the chemical and the nature and amount of any impurities must be known. The chances of detecting carcinogenicity are greatly enhanced when testing is conducted in several species of animals. The outcome may also be altered by the route of exposure and dosage. In many studies, the results are difficult to evaluate, especially in the case of benign tumors. It is necessary to distinguish between truly benign tumors and those lesions that are premalignant or potentially malignant; the distinction is not always possible. These tests only attempt to divide chemicals into carcinogens and noncarcinogens. Considerably more research related to risk assessment is necessary to provide a basis for regulatory action. (2 refs)

- 79-0008 Structure-Activity Studies of Chemical Carcinogens Using Quantum Chemical Methods.** (Eng) Loew, G. H. (Stanford Univ. Medical Center, Stanford, CA); Pack, G. R. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 197-199; 1978.

The use of quantum chemical methods to calculate molecular descriptors that have a meaningful relationship to carcinogenic potencies is discussed. Current knowledge of the steps leading to chemical carcinogenesis permits a classification into chemical families, whose individual members follow the same general pathways. The electronic structures and electrophilic reactivity of candidate ultimate carcinogens can be cal-

culated and used to test the electrophilic hypothesis of ultimate carcinogens. (9 refs)

- 79-0009 A Computerized Toxicity Estimation System.** (Eng) Enslein, K. (Genesee Computer Center, Rochester, NY, 14605). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 82-87; 1978.

A computerized toxicity estimation system is presented and discussed. The proposed toxicity estimation model begins with 549 compounds from the 1974 "Toxic Substances List". These compounds are assigned partition coefficients and substructure codes that are fed into the computer data base. The modeled dependent variable is the "Rat Oral LD-50". Subpopulations are then generated by clustering and discriminant analysis. Two groups, high toxicity compounds and lower toxicity compounds, are finally analyzed through the derivation of regression equations. Discriminant analysis revealed a group of 31 compounds that did not fit into the larger group pattern. These were the most highly toxic compounds; and a discriminant equation was set up utilizing the 134 most often used fragments, mol wt, partition coefficient data, and various other interactions with a final set of 12 terms demonstrating significant predictive value. Results of regression analysis revealed the most important predictive parameter to be mol wt. Although Rat Oral LD-50 was used as the endpoint of this analysis, it is suggested that carcinogenesis applications of this method would follow similar lines. (2 refs)

- 79-0010 Carcinogen Binding to DNA.** (Eng) Neidle, S. (Dept. Biophysics, King's Coll., London, England). *Nature* 276(5687): 444-445; 1978.

The latest information on the interaction of a chemical carcinogen and its target molecule is reviewed. Polycyclic aromatic hydrocarbons are not directly carcinogenic but are metabolized in vivo to short-lived reactive species that bind to cellular macromolecules. Most evidence indicates that DNA is the critical receptor, but why the interactions of the reactive species with DNA are carcinogenic remains unknown. An important metabolite of benzo(a)pyrene is its 7,8-diol-9,10-epoxide, which binds predominantly to guanine residues in DNA, mainly at the N2 or N7 position. Circular dichroism spectroscopy showed that the BP diol epoxide was bound to the dinucleoside phosphate GpU at the N2 position of the guanine base. This interaction profoundly altered the conformation of the molecule around the guanine-sugar linkage, such that if it were in a double strand, the guanine would be forced out of its base-pairing position.

Several aromatic electrophilic carcinogens were analyzed for their ability to unwind closed, circular, supercoiled simian virus 40 DNA. Almost all compounds produced unwinding, although striking differences were noted among individual compounds. Unwinding ability was strongly correlated with frameshift mutagenic activity in a *Salmonella* Ames test. Thus, local unwinding of DNA is probably the consequence of the covalent binding of an active compound. This information was used to construct a plausible molecular model for the structure of the DNA adduct. In similar unwinding experiments, analyses of the S₁ nuclease-treated product showed that predominantly adenine residues were modified to cause local unwinding-induced denaturation, even though the guanine residues were the major sites for actual binding of carcinogen. It is suggested that there are at least two categories of base modification: adenine involvement, producing local unwinding and base-pair cleavage, and guanine attachment, with a less-drastic result. (no refs)

- 79-0011 Various Parameters Associated with Mutagenesis.** (Eng) Clive, D. (Burroughs Wellcome Co., Research Triangle Park, NC). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 22-26; 1978.

The advantages and disadvantages of various mutagenicity assay systems are considered. Most mutagenicity measurements have been made in bacteria, but bacteria may not be the best basis for predicting mutagenicity and carcinogenicity in humans. Studies involving x-ray- and ethyl methanesulfonate-induced mutations in organisms of various sizes indicate that the sensitivity of a gene to a mutagen may depend on the type of organism bearing the gene and, in particular, on the size of the genome surrounding the target gene. The target size of the gene grows with the complexity of the organism carrying that gene. Of the various mutagenicity assay systems available (mouse specific-locus test, mammalian dominant lethal assay, insect assays, mouse recessive lethal assay, bacterial assays, and cultured mammalian cells), cultured mammalian cells may represent the best system for predicting effects in humans. This assay is inexpensive, fast, sensitive, can use large numbers of cells, can be used with exogenous mammalian metabolism, and can detect both gene and chromosomal mutations. Its disadvantages included the facts that exogenous metabolism may not be the same as in vivo metabolism and that it measures mutagenic potential only and not actual in vivo mutagenesis. (10 refs)

- 79-0012 Regulatory Considerations Concerning Mutagenesis.** (Eng) Kolbye, A. C. (Bureau Foods, Food and Drug Admin., Washington, DC, 20204). *J Soc Cosmet Chem* 29(11): 727-732; 1978.

The usefulness of the available mutagenesis test systems as a basis for regulatory decision-making is considered from the point of view of the Food and Drug Administration (FDA). The Ames mutagenesis test has many attractive features, including the ability to assess the mutagenic potency of a substance quantitatively over a very wide range of dosage. The Ames test is sensitive enough to detect the majority of chemical carcinogens presently identified as such, except for hormones, metals, and carcinogens dependent on physicochemical effects. It is fairly specific for the substances tested in that mutagenic effects have been detected for many carcinogens. However, the question of false-positive results has not been resolved yet and will only be settled by expanding the number of chemicals tested. Although the Ames test can quantitatively measure mutagenic strength over an exceedingly broad range of dosage, it does not measure penetrability of the substance in the intact animal or selective parameters such as biological resistance. It is recommended that more effort be devoted to expanding the number of substances tested to gain more insight into the specificity of the system to detect mutagenic carcinogens. Premature regulatory decisions may create unanticipated controversies. (5 refs)

- 79-0013 Environmental Mutagens and Carcinogens.**
(Eng) Nagao, M. (Nat'l. Cancer Center Res. Inst., Chuo-ku, Tokyo 104, Japan); Sugimura, T.; Matsu-shima, T. *Annu Rev Genet* 12(1): 117-159; 1978.

Various types of environmental mutagens are reviewed, and other factors related to the detection and study of these substances are discussed. Mutation tests using microbes, an in vitro transformation test using cultured mammalian cells, other short-term test systems for the detection of environmental mutagens and carcinogens, and in vivo long-term animal tests for environmental carcinogens are described. Naturally occurring agents include those produced by fungi and plants and fatty acid peroxides in foods. Among those produced by fungi, aflatoxin B₁ is the strongest mutagen and carcinogen. Proven or possible mutagens and/or carcinogens produced by other plants include cycasin, substance(s) in bracken fern, pyrrolizidine alkaloids, flavonoids, quercetin, hydrazine, safrole, isosafrole, dihydrosafrole, monocrotalin, and heliotrine. The fatty acid peroxide, malonaldehyde, has been found to be mutagenic to *Salmonella typhimurium* TA1978. Another source of environmental mutagens is pyrolysis products, which include cooking products, tobacco tar, and aromatic hydrocarbons. Other sources discussed include nitrosation products, synthetic chemicals (food additives, cosmetics, drugs, pesticides, household materials, and occupational substances and industrial intermediates), and water pollutants and air pollutants. In addition, factors modifying mutagenesis and carcinogenesis, evaluation and quantitation of data, and overlapping of mutagens and carcinogens are discussed. (311 refs)

- 79-0014 The Importance of Metabolic Considerations.**
(Eng) Clayson, D. B. (Eppley Inst., Omaha, NB,

68105). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 38-44; 1978.

The first two phases of carcinogenesis, the metabolic activation of procarcinogens and the interaction of the resulting electrophile with cellular macromolecules (DNA, RNA, and protein) are surveyed. Conversion into electrophiles is accepted as the key to the metabolic activation of most major classes of environmental carcinogens, including polycyclic aromatic hydrocarbons, alkylating agents, nitrosamides, nitrosamines, and aflatoxins. Concerning electrophile-DNA binding, infidelity in DNA replication has been shown to be induced by 0-6 but not N-7 methylation of guanine. The realization that carcinogens need metabolic activation and that the success of the *Salmonella* and other microbial tests depends not only on the use of suitable test bacteria but also on the addition of metabolic enzymes or microsomes (plus necessary cofactors) to the system increased the parallelism between mutagenicity and carcinogenicity test results. In vivo metabolic assays, nonspecific agents can modify metabolism and thus the proportion of a procarcinogen dose that is converted to an ultimate carcinogen. These agents include enzyme inducers, specific enzyme cofactors, enzyme poisons, antioxidants, hormones, and compounds that affect the nutritional status of the test animals. (24 refs)

- 79-0015 Carcinogenic Risk Estimation for Chloroform: An Alternative to EPA's Procedures (Letter to Editor).** (Eng) Reitz, R. H. (Toxicology Res. Lab., Dow Chemical Co., 1803 Building, Midland, MI, 48640); Gehring, P. J.; Park, C. N. *Food Cosmet Toxicol* 16(5): 511-514; 1978.

A discussion is presented that evaluates the overestimation of the magnitude of the cancer risk from chloroform as estimated by the Environmental Protection Agency (EPA) from data generated at NCI. There are two reasons why this particular risk extrapolation is probably inaccurate. First, the EPA has failed to consider important data concerning the mechanisms through which chloroform exerts its toxicity. The mathematical model used by the EPA for species/species extrapolation assumes direct cytotoxicity of the chemical in question. However, the toxicity of chloroform is apparently due not to the parent molecule itself, but rather to the production of reactive metabolites that bind covalently to tissue proteins. This difference has led to a major error in extrapolating from laboratory rodents to man. Secondly, the NCI study was carried out with very high doses of chloroform. However, there is evidence of a sudden change in the shape of the dose-response curve of chloroform when the dose falls below 200 mg/kg, resulting in a sharp decrease in oncogenicity. This latter finding suggests that there may be detoxification mechanisms that effectively protect the animals until they are overwhelmed by very large doses. In view of the fact that the

EPA has, on the basis of the NCI study, proposed an amendment to the Safe Drinking Water Act establishing a Maximum Contaminant Level of 0.1 ppm of chloroform, it is suggested that the risk estimation be performed as accurately as possible so that the risk/benefit ratio may be properly considered. (no refs)

- 79-0016 Trichloroethylene: Hepatic Effects, Metabolism and Elimination.** (Eng) Cooper, P. (No affiliation given). *Food Cosmet Toxicol* 16(5): 491-492; 1978.

Studies concerning the metabolism, elimination, and hepatic effects of trichloroethylene (TCE) are reviewed. These include investigations of the relationship between the degree of exposure and the excretion of the solvent and its metabolites, and the relationship between the hepatotoxicity of TCE and its metabolism. Metabolites formed during the microsomal metabolism of TCE and impurities and additives contained in technical grade TCE are also discussed. (11 refs)

- 79-0017 Carcinogenicity of Esters and Benzylic Alcohols.** (Eng) Poirier, L. (NCI, Bethesda, MD, 20014); Helmes, C. T. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 179-183; 1978.

A review of the structure-activity relationships of carcinogenic and noncarcinogenic esters indicated that the carcinogenic activity of carboxylic esters (CE's) is independent of the structure of the acid portion of the molecule. CE's whose alcohol portion is extensively stabilized by resonance or induction are likely to be carcinogenic, but CE's whose potential carbonium ion is minimally stabilized by resonance or induction are unlikely to be carcinogenic. These generalizations apply only to CE's since carboxylate ion is a weak leaving group. However, stabilization of the ensuing carbonium ion is helpful in carcinogenesis. Investigation of the carcinogenic potential of benzylic alcohols has failed to reveal a structure-activity relationship for carcinogenesis, although there is suggestive evidence that benzylic alcohol formation is a potential major route of carcinogen activation. (15 refs)

- 79-0018 Structural Parameters Associated with Carcinogenesis (Halogenated Olefins, Vinyl and Allyl Analogs and Epoxides).** (Eng) Fishbein, L. (Nat'l. Center Toxicological Res., Little Rock, AR, 72207). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in*

Annapolis, 31 August-2 September 1977. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 8-21; 1978.

A number of reportedly carcinogenic industrial compounds (including halogenated olefins, vinyl and allyl analogs, and epoxides) were examined to determine if their structural, biological, and metabolic similarities could help predict their carcinogenicity. The chlorinated olefinic derivatives of major concern are vinyl chloride, vinylidene chloride, trichloroethylene, chloroprene, dichlorobutene, and perchloroethylene, all of which have been proved to be carcinogenic to humans and/or laboratory animals. Evidence suggests that all chlorinated ethylenes are metabolized to oxiranes (epoxides) as a first step. The oxiranes, which are strongly electrophilic, may react directly with cell nucleophiles or they may undergo intramolecular arrangements. No such structure-activity relationship has been demonstrated for the various vinyl and allyl analogs that are carcinogenic and/or mutagenic. In the case of the epoxides, the presence of a reactive functional group (as in epichlorohydrin) or a double bond (as in glycidaldehyde) near the epoxide appears to enhance carcinogenicity by allowing the chemical to act as a difunctional alkylating agent for macromolecules. Greater reliance should be placed on mutagenicity testing and on definitive metabolic and pharmacokinetic studies to augment structure-activity predictions of carcinogenicity. (79 refs)

- 79-0019 Analyses of Epoxides, Haloethers and Related Compounds.** (Eng) Goldschmidt, B. M. (New York Univ. Medical Center, New York, NY, 70016). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 113-119; 1978.

In attempt to distinguish between carcinogenic and noncarcinogenic exposures, female Swiss ICR/Ha mice were treated topically with 12 aliphatic monoepoxides starting at age 6 wk continuing for at least 1 yr. Of 30 animals treated with epoxypropanol, 8 developed papillomas that progressed to squamous carcinomas. Other active compounds were epoxybutene and epoxyhexadecane, which induced papillomas in 3/30 and 2/20 animals, respectively, but only one squamous carcinoma (epoxyhexadecane). In mouse skin tests with eight other monoepoxides (6 cyclic and 2 vicinal to a ring), only styrene oxide was active, inducing papillomas in 3/30 animals and one squamous carcinoma. Similar mouse skin studies with 11 aliphatic diepoxides revealed that, unlike the monoepoxides, most were carcinogenic. The incidence of papillomas, followed by the number of squamous carcinomas, caused by the most active compounds was as follows: 1,2,3,4-diepoxbutane, 10/30 (6); 1,2,4,5-diepoxypentane, 10/30 (3); 1,2,5,6-diepoxhexane, 13/30 (10); 1,2,6,7-diepoxheptane, 9/30 (1); 1,2,7,8-diepoxyoctane, 7/30 (4); and vinyl

cyclohexenediepoxyde, 14/40 (9). Studies of the reaction rates of the carcinogenic diepoxides with various nucleophiles showed that differences in second order rate constants were insufficient to distinguish between these compounds and the noncarcinogenic monoepoxides. Of 10 haloethers (α -chloroethers) tested by skin application or sc injection, 9 induced sarcomas by injection. The most potent compounds were bis(chloromethyl)ether (BCME) and chloromethyl methyl ether (CMME), which induced sarcomas in 21/50 and 10/30 animals, respectively. In the skin tests, BCME caused 13 papillomas and CMME no papillomas in 20 animals, which indicates that haloether carcinogenicity through skin application requires a bifunctional structure as in epoxides. The carcinogenic potential of a homologous series of haloethers related to BCME and CMME decreased with an increase in methylene groups between the two chloroether functions. (23 refs)

79-0020 The Carcinogenic Effect of Polycyclic Aromatic Hydrocarbons. (Ger) Contag, B. (Fachbereich Chemie, Technische Fachhochschule Berlin, Limburger Strasse 20, D-1000 Berlin 65, W. Germany). *Z Naturforsch C* 33(9/10): 651-659; 1978.

Theories on the mechanism of action of polycyclic aromatic hydrocarbons (electron, metabolite and matrix theories, the latter being a synthesis of some elements of the other two theories) are discussed. The matrix theory is based on the assumption that specific adsorption of the hydrocarbon molecules occurs on certain, as yet unknown, tissue components, and that there is a good geometric and energetic compatibility between these reaction partners. The function of the tissue component, e.g., an enzyme, can be inhibited by the adsorption of the carcinogen. Nuclear DNA is currently believed to be the receptor molecule for the carcinogen. This belief is supported by the fact that the covalent binding of the hydrocarbon molecules to the DNA bases implies a somatic mutation, and that the action of other carcinogens (aromatic amines, azo dyes, alkylants) can also be attributed to such a mechanism. The electrophilic metabolites of the polycyclic aromatic hydrocarbons also react, however, with a great number of other macromolecules, such as proteins. (79 refs)

79-0021 Quantum Chemically Based Predictions of Polycyclic Aromatic Hydrocarbon Carcinogenicity - The Bay Region Theory. (Eng) Lehr, R. E. (Univ. Oklahoma, Norman, OK, 73019); Levin, W.; Wood, A. W.; Conney, A. H.; Yagi, H.; Jerina, D. M. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 129-135; 1978.

In an attempt to determine the general importance of the diol epoxide pathway in the activation of polynuclear aromatic hydrocarbons to mutagens and carcinogens, quantum-chemical calculations were used to predict biological activity. A model was chosen that enabled calculation of the relative ease of benzylic carbonium ion formation from various diol epoxides based upon the finding that both cis- and trans- addition of water occurs in the hydration of the stereoisomeric benzo(a)pyrene 7,8-diol,10-epoxide. In order to assess the energy change that occurs upon the conversion of the diol epoxide to a benzylic triol carbonium ion, only the pi-electron energy change is considered. This calculation is then accomplished using the perturbational molecular orbital (PMO) approach. Results have shown a favorable correlation between predictions based upon the PMO calculations and the available data on mutagenicity and carcinogenicity of PAH and their derivatives: for a given PAH, diol epoxides in which the oxirane oxygen atom formed a part of a "bay region" were invariably calculated to be the most reactive metabolically possible diol epoxides of that PAH, and this evidence was confirmed by tests with benz(a)anthracene and its appropriate derivatives. (20 refs)

79-0022 Hydrazines: Occurrence, Analysis and Carcinogenic Activity as Related to Structure. (Eng) Schmeltz, I. (American Health Foundation, Valhalla, NY, 10595); Hoffmann, D.; Toth, B. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 172-178; 1978.

The occurrence, analysis and carcinogenic activity of hydrazines as related to structure are reviewed. Although hydrazines have received relatively little attention compared with other chemical carcinogens, a group of 37 hydrazines have been reported to induce tumors in laboratory animals. These include monoalkyl-, dialkyl- (symmetrical and unsymmetrical), trialkyl- and tetra-alkyl hydrazines, in addition to various hydrazides: maleic hydrazide, succinic acid-2,2-dimethylhydrazide, and isoniazid. Evidence suggests that most hydrazines are tumorigenic in the lungs and blood vessels, while all should be suspect pending animal studies. Degree of alkylation does not correlate with carcinogenic activity, and no structure-activity relations have been demonstrated except for a series of hydrazines where substitution on both nitrogens accounts for organospecificity. It is contended that different hydrazines have different mechanisms of action: hydrazine itself may react with a one- or two-carbon fragment during metabolism resulting in an acylating agent, or it may react directly with DNA to remove pyrimidine bases, although its exertion of tumorigenicity as an alkylating compound is difficult to visualize. Even though conclusive animal studies reveal the oncogenic nature of hydrazines as a group, epidemiological evidence is required before these observations are extrapolated to humans. (52 refs)

REVIEW

- 79-0023 Metabolic Activation of Aromatic Amines.** (Eng) King, C. M. (Michigan Cancer Foundation, Detroit, MI, 48201). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 140-147; 1978.

Enzymatic, cellular, and metabolic studies were reviewed in order to determine the complex molecular events involved in the metabolic activation of carcinogenic aromatic amines. One mechanism of activation of arylhydroxamic acids results from the formation of nitroxide-free radicals by one-electron oxidants. A second mechanism by which aromatic amine derivatives may be activated is based on the finding that seryl-transfer RNA synthetase could esterify 4-hydroxylaminoquinoline N-oxide to a product capable of reacting with nucleic acid. Additionally, an N-Oarylhydroxamic acid acyltransferase had been implicated in metabolic activation as follows: the acyl group is first transferred to the oxygen of the arylhydroxylamine, giving rise to an acyloxyamino derivative that can react spontaneously with nucleic acids or proteins. Even closely related tissues may differ widely in their susceptibility to tumor induction by a single compound as a result of different levels of an activating enzyme. The mutagenic potential of metabolic activation by acyltransferase was studied in *Salmonella typhimurium* strain TA 1538, which was exposed to the carcinogen acetylaminofluorene (AAF) in the presence and absence of an S-9 liver microsome fraction. The results showed that bacterial metabolism may be responsible for the terminal activation of 2-AAF derivatives. A good correlation was also demonstrated between the ability of arylhydroxamic acids to combine with nucleic acids and their ability to cause mutations in *Salmonella*. (18 refs)

- 79-0024 Polynuclear Aromatic Hydrocarbons: Occurrence, Formation, and Carcinogenicity.** (Eng) Hoffmann, D. (American Health Foundation, Valhalla, NY, 10595); Hecht, S. S.; Schmeltz, I.; Wynder, E. L. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 120-128; 1978.

A review of the occurrence, formation, and carcinogenicity of polynuclear aromatic hydrocarbons (PAH) is presented. PAH are formed during heating and combustion of fossil fuels and other organic compounds. Due to their characteristically low vapor pressures and water insolubility, they are ubiquitous in the environment, concentrating in particulate matter in the air, in water, in sediments, and in soil. The environmental synthesis of PAH is a two-step process: first, pyrolysis of organic matter leads to the formation of CH radi-

cals, and second, the radicals combine to produce thermodynamically preferred aromatic products. Epidemiological studies suggest that the main concern should be PAH content of tobacco smoke, air, and occupational settings, although it is known from model studies that PAH-containing inhalants do not necessarily induce lung cancer but rather act as initiators of malignancy for a subsequent insult by other carcinogens, cocarcinogens and promoters. Several four-ring parent and alkyl substituted aromatic hydrocarbons and many methylated and unsubstituted five- and six-ring hydrocarbons are carcinogenic in experimental animals. Most carcinogenic PAH have at least one free K-region and at least one unsubstituted angular ring. It is suggested that the carcinogenic PAH are metabolically activated in the angular ring to epoxides or dihydroxyepoxides. (52 refs)

- 79-0025 Aromatic Amines and Azo Dyes.** (Eng) Irving, C. C. (Veterans Administration Hosp., Memphis, TN). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977.* Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 136-139; 1978.

A review of the aromatic amines and azo dyes is presented. The most potent carcinogenic aromatic amines are those with two or three aromatic rings and with the amino group in the para position. A list of these active compounds includes benzidine, 2-naphthylamine, 4-aminobiphenyl, 2-aminofluorene, 4-aminostilbene, 2-aminophenanthrene, and 2-aminoanthracene. Monocyclic aromatic amines and aromatic amines with more than three rings are inactive or, at best, very weak carcinogens. Carcinogenic azo dyes are divided into two categories, the derivatives of p-aminoazobenzene, and those subject to reduction cleavage that yields carcinogenic aromatic amines. Structure activity relationships allow prediction of carcinogenic activity based on the reduction products of the azo compound. The reactions that are likely to be involved in the metabolic activation of aromatic amines are N-hydroxylation, conjugation, and acyl transfer, with one or more metabolic reactions (which are different in various susceptible tissues) requisite for oncogenicity. It is concluded that both the extent of metabolic activation and the absolute reactivity of the activated metabolites are highly dependent upon the structure of the aromatic amine. (17 refs)

- 79-0026 Hair Dyes and Breast Cancer (Letter to Editor).** (Eng) Burnett, C. M. (Clairol Inc., Stamford, CT, 06902); Menkart, J. *N Engl J Med* 299(22): 1253; 1978.

Factors that should be considered when evaluating the possible association between hair dyes and breast cancer are discussed. Almost all aromatic amines that induce breast cancer in rodents are conjugated or fused rings, whereas most oxida-

tive hair dyes are simple ring structures. In addition, none of 13 hair dyes tested in the NCI bioassay program caused cancer of the breast or any reproductive organ in mice. (11 refs)

- 79-0027 Complications of Prenatal Therapy with Diethylstilbestrol.** (Eng) Herbst, A. L. (Registry Res. Hormonal Transplacental Carcinogenesis, Chicago Lying-In Hosp., 5841 S. Maryland Ave., Chicago, IL, 60637); Scully, R. E.; Robboy, S. J.; Welch, W. R. *Pediatrics* 62(6, part 2, Suppl): 1151-1159; 1978.

Epidemiological, pathological, histological, and clinical data on clear cell adenocarcinoma (CCA) cases accessioned in the Registry for Research on Hormonal Transplacental Carcinogenesis (Chicago, Illinois) are reviewed, along with data on the histogenesis of diethylstilbestrol (DES)-associated genital abnormalities. The maternal hormone history was fully investigated in 292/333 registry CCA cases, and in approx 66% of the 262 cases the mother was treated with DES or the chemically related compounds dienestrol and hexestrol. Max daily doses of DES ranged from 1.5 to 150 mg, total doses from 135 to 18,200 mg. In most cases the drug was administered for high-risk pregnancy. The incidence curve shows a sharp rise beginning at age 14, a peak at age 19, and a sharp decline through age 22. Overall risk estimates of developing CCA range from 0.14 to 1.4/1,000 for DES-exposed women through age 24. CCA is diagnosed most efficiently by pelvic examination and cytology. Lower genital tract changes in DES-exposed women without cancer include vaginal adenosis, vaginal or cervical transverse ridges, and cervical ectropion. These changes are more common in women exposed in the second mo of fetal life or earlier. Vaginal changes in DES-exposed subjects may result from a disturbance of the müllerian epithelium and/or the vaginal plate, resulting in the persistence of müllerian cells at a level below that of their normal termination near the external os of the cervix. Similarly, the vaginal or cervical ridges may be the result of abnormal proliferation of connective tissue at the junction of the müllerian and urogenital-sinus anlage. Other observations suggest the possibility of a primary stromal action of DES. (28 refs)

- 79-0028 The Newborn Mouse as a Model for Study of the Effects of Hormonal Steroids in the Young.** (Eng) Kohrman, A. F. (Coll. Human Medicine, Michigan State Univ., East Lansing, MI, 48824). *Pediatrics* 62(6, part 2, Suppl): 1143-1150; 1978.

The use of fetal and neonatal mice to study the effects of steroidal and nonsteroidal compounds on development and carcinogenesis is discussed. Administration of estradiol, progesterone, testosterone, or diethylstilbestrol to mice younger than 5 days results in permanent vaginal and cervical changes in the adult with permanent alterations in the rates

of DNA, protein, and RNA synthesis in the affected tissues. A small but significant number of the animals treated with one of the first three hormones developed malignant lesions, mostly epithelial in nature, in the vaginal and cervical areas. The mouse appears to be an appropriate model for studying similar steroid-induced lesions in humans. Neonatal treatment with diethylstilbestrol appears to elevate cyclic AMP levels in the vaginal tissues. It is hypothesized that the primary effect of this treatment is to increase the rates of proliferation of the basal cell population from which the adult cervico-vaginal epithelium ultimately derives. The carcinogenesis resulting from neonatal or intrapartum steroid treatments may therefore be regarded as a form of teratogenesis. Cervico-vaginal changes have also been observed after neonatal treatment of mice with progestones. The mouse model may be useful for estimating the risk of further exposure to steroid hormones in women exposed to diethylstilbestrol in utero. It may also be useful in studies of prophylaxis of steroid-induced lesions or other abnormalities arising from neonatal challenges. (20 refs)

- 79-0029 Hormones and the Liver (Meeting Abstract).** (Eng) Lunzer, M. (Liver Unit, Dept. Gastroenterology, Royal North Shore Hosp., Sydney, NSW, Australia). *Aust NZ J Med* 8(6): 677; 1978. (no refs)

- 79-0030 General Discussion.** (Eng) Nordin, B. E. (MRC Mineral Metabolism Unit, General Infirmary, Great George St., Leeds LS1 3EX, England); Lemon, H. M.; Rakoff, A. E.; Utian, W. H.; van Keep, P. A.; Lauritzen, C.; Keller, P. J.; McKay Hart, D.; Van der Does, C.; Studd, J. W.; Kopera, H.; Rauramo, L.; Baulieu, E. E.; Neves e Castro, M.; Mack, T. M.; Haspels, A. A.; Vooijs, G. P.; Thijssen, J. H.; de Waard, F. In: *Front Horm Res* 5: 248-260; 1978.

A general discussion of papers presented at a conference on the risks and benefits of estrogen therapy is reported. It was concluded that the epidemiologists have made a very strong case for there being some connection between estrogen therapy and an increased risk of endometrial cancer, but as far as breast cancer is concerned the question is still open. However, estrogen therapy is still valuable for the treatment and prevention of estrogen deficiency. (no refs)

- 79-0031 Clinical and Experimental Aspects of the Anti-Mammary Carcinogenic Activity of Estriol.** (Eng) Lemon, H. M. (Dept. Internal Medicine, Univ. Nebraska Medical Center, 42nd St. and Dewey Ave., Omaha, NB, 68105). In: *Front Horm Res* 5: 155-173; 1978.

The results of a large-scale experiment in which estriol and 23 other natural and synthetic hormones were evaluated for antimammary carcinogenic activity in > 2,600 female Spra-

REVIEW

gue-Dawley rats are reviewed, and brief mention is made of the effects of estriol on human postmenopausal metastatic breast carcinoma. Max reduction in the incidence of breast carcinomas (80%-90%) occurring during the natural life span of the rats was achieved when pellets containing 600-1,300 μg estriol were implanted sc every 2 mo, beginning 48 hr before po administration of 20 mg 7,12-dimethylbenz-(a)anthracene or 50-70 mg procarbazine (PC). Estriol doses that were lower or given more frequently than 100-200 $\mu\text{g}/\text{kg}/24$ hr every 2 mo were less effective. Estrone also significantly reduced breast carcinoma incidence; five other compounds produced a statistically insignificant reduction of incidence, especially in PC-treated rats. Estriol did not reduce the number of breast cancers induced by γ -radiation, and it did not reduce the incidence of other types of neoplasms. Estriol reduced the uterine wts of carcinogen-treated rats by 20%-25%. Estriol probably functions as a mammary anti-cocarcinogen by impeding ovarian estradiol stimulation of breast duct and alveolar cell replication, preventing the 10^{10} cell generations necessary for a palpable 1.0-cm tumor to become apparent. Experiments show that its action is comparable to that of castration. Human studies indicate excellent tolerance for po estriol doses of 10-200 $\mu\text{g}/\text{kg}/24$ hr, which may correct subnormal estriol/estrone + estradiol urinary quotients associated with elevated breast cancer risk. (36 refs)

- 79-0032 A Review of the Evidence Linking Estrogens and Cancer in Animals.** (Eng) Hertz, R. (Dept. Pharmacology, George Washington Univ. Medical Sch., Washington, DC, 20006). *Pediatrics* 62(6, part 2, Suppl): 1138-1142; 1978.

Evidence of the association between estrogen administration and subsequent tumor development in animals is reviewed. Tumors of the breast, cervix, endometrium, ovary, pituitary, testicle, kidney, and bone marrow have been induced reproducibly in the mouse, rat, rabbit, hamster, squirrel monkey, and dog by estrogens. However, the repeated failure of similar experiments to elicit a tumor response in rhesus monkeys has fostered skepticism of the potential relationship of these findings to humans. The animal studies have identified major critical factors in tumor induction by exogenous estrogens: genetic or ethnic derivation, dose, age, chronicity of exposure, and potential presence of predisposing viruslike factors. The genetic factor appears most applicable to humans, particularly in relation to breast cancer. Steroids exhibit a continuous spectrum of biological effects. The specificity of the biological effects of many steroids is relative rather than absolute, and a considerable degree of overlap is frequently encountered. There is a lack of specificity in the chemical structures of compounds having estrogenic and tumorigenic potency. The estrogenic response among hormonally induced tissue effects has the least specific structural requirements. It is suggested that the estrogenic response alone can be elicited by a wide variety of chemical agents. (37 refs)

- 79-0033 Estrogen Receptor Binding and Growth of the Reproductive Tract.** (Eng) Clark, J. H. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX, 77080); Hardin, J. W.; McCormack, S. A. *Pediatrics* 62(6, part 2, Suppl): 1121-1127; 1978.

The mechanism of action of estrogen and its relationship to normal and abnormal estrogen-induced growth are discussed. In hormone-sensitive cells, estrogen is bound to cytosol receptors (Rc) in the cell, the binding resulting in the formation of receptor-estrogen complexes that undergo translocation to acceptor or nonacceptor nuclear sites. Nuclear binding of these complexes results in the replenishment of Rc sites. A single injection of estradiol in a female rat stimulates all late uterotrophic events, whereas a single injection of estriol or dimethylstilbestrol stimulates all early uterotrophic events but not uterine growth. Serial injection of estriol or use of estriol implants results in true uterine growth. Nonsteroidal estrogen antagonists are slowly cleared from their nuclear binding sites and cause prolonged stimulation of uterine growth. These compounds appear to have estrogenic properties in some cell types (epithelium), while acting as estrogen antagonists in others. Differential stimulation of the epithelial cells may account for the tumorigenic effects of nafoxidine and clomiphene. It is suggested that estrogen agonists and antagonists should be classified as short-acting or long-acting, the long-acting estrogens being further subdivided into two classes. Great caution should be applied when long-acting estrogens are used in humans. (32 refs)

- 79-0034 Neuroleptic-induced Prolactin Level Elevation and Breast Cancer. An Emerging Clinical Issue.** (Eng) Schyve, P. M. (Lab. Biological Psychiatry, Illinois State Psychiatric Inst., 1601 W. Taylor St., Chicago, IL, 60612); Smithline, F.; Meltzer, H. Y. *Arch Gen Psychiatry* 35(11): 1291-1301; 1978.

Literature on the possible link between breast cancer (BC) and prolactin (PL) is reviewed, particularly the evidence that neuroleptics may increase BC risk via their effects on PL secretion. All available neuroleptics, including reserpine, raise serum PL levels by limiting the interaction of dopamine with receptors that, by an unknown mechanism, markedly suppress PL secretion. In addition, there is a strong interaction between estrogens and reserpine or phenothiazines in disinhibiting PL secretion. Reserpine was significantly more effective in increasing plasma PL levels in rats given exogenous estrogen than in control rats. An elevated serum PL level increases the incidence of spontaneously occurring mammary tumors in mice and increases the growth of established carcinogen-induced mammary tumors in rats. However, caution is necessary in extrapolating experimental data to human mammary tumors, because human and rodent tumors differ in some important characteristics, including hormone responsiveness. Serum PL levels in women with, or at risk for, BC have generally been normal, and only a minority of human mammary tumors have been found to respond to

changes in serum PL levels. Epidemiologic studies have failed to demonstrate an increased risk of BC associated with the use of neuroleptics or reserpine. Thus, although some human mammary tumors are PL-dependent, the available evidence does not demonstrate an increased risk of BC in women receiving neuroleptics. (136 refs)

79-0035 Relationships Between the Epidemiology and Endocrinology of Mammary Carcinoma. (Eng)

de Waard, F. (Instituut voor Sociale Geneeskunde, Rijksuniversiteit Utrecht, Bijlhouwerstraat 6, Utrecht, Netherlands). In: *Front Horm Res* 58: 145-154; 1978.

Current information on the epidemiology of breast cancer is reviewed and related to endocrinological factors. The roles of prolactin, androgens, and estrogens are summarized briefly. The relationship between breast cancer and menopause, geographical differences in the incidence of breast cancer, and the relationship of body size and the development of breast cancer are also discussed. Age-specific incidence curves suggest that from an epidemiologic point of view, breast cancer occurring before and after menopause are two different entities. Differences in incidence between Western and non-Western countries are more profound after menopause than before. It is not desirable to adjust wt for height when analyzing the effects of wt and height on breast cancer risk; actually, height itself has been shown to be a risk factor. Further experiments should be aimed at investigating the relation of androgen and estrogen metabolism to body size and mass. (38 refs)

79-0036 Postmenopausal Carcinoma as a Result of Estrogen Treatment: Survey of Evidence. (Eng)

Mack, T. M. (Dept. Community and Family Medicine, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90007). *Pediatrics* 62(6, part 2, Suppl): 1104-1113; 1978.

Recent studies of the relationship between exogenous estrogen administration and endometrial cancer are reviewed, along with objections to these studies. The objections are classified into three groups: illogical, logical but cannot reasonably explain the available data, and logical and applicable. Findings that positively support an etiologic hypothesis are the magnitude of the relative risk estimates, the consistency of the studies internally and externally, the consistency of the internal evidences of interaction (dose-response or duration-response relationships, tendency for highest risk from estrogen to occur in women normally at low risk) with a biologic relationship, and the specificity of the association with respect to other drugs, which rules out a nonspecific ascertainment bias. Credibility is enhanced by a lack of specificity in the findings with respect to various classes of steroidal and nonsteroidal estrogens. Two important criticisms remain to be answered. The first is the possibility that estrogen use is only a surrogate for another determinant of endometrial cancer. A woman may be at high risk either

because of her treatment or because of the reasons she was selected for treatment. The second is the possibility that some or all of the association is due to pathologists conservatively or mistakenly classifying hyperplasia as neoplasia. However, the bulk of evidence from reevaluation studies is strongly against an explanation based on misclassification of hyperplasia. Even when the most serious reservations are considered, it is difficult to avoid the tentative conclusion that estrogens are causally linked to endometrial cancer and that the attributable risk is numerically sizeable. (34 refs)

79-0038 Oral Contraceptives--Possible Mediation of Side Effects via an Estrogen Receptor in Liver.

(Eng) Eisenfeld, A. J. (Yale Univ. Sch. Medicine, New Haven, CT, 06510); Aten, R. F.; Weinberger, M. J. *Biochem Pharmacol* 27(22): 2571-2575; 1978.

A review of evidence is presented to support the concept that most of the side effects caused by oral contraceptives (throm-

REVIEW

bosis, heart attacks, hypertension, gallbladder disease and liver tumors) are due to an estrogen interaction in the liver. Estrogen binding was readily detectable in liver cytosol prepared from adult female rats. The liver estrogen receptor increases 5- to 10-fold at about the time of puberty in the rat. The cytoplasmic receptor-steroid complex translocates from the cytoplasm to the nucleus, where it attaches to chromatin. The translocation has been demonstrated both in vitro and in vivo in rats. If some of the major side effects of oral contraceptives are mediated by a receptor-estrogen interaction in liver, their safety might be improved if this liver interaction could be minimized while maintaining the useful effects in the hypothalamic-pituitary axis and in the endometrium. This goal might be accomplished by exploiting some functional difference between the estrogen receptor in the hypothalamus, pituitary, and uterus. The newer combined oral contraceptives contain lower amounts of both the estrogen (ethinyl estradiol) and of the progestin. Decreasing the amount of ethinyl estradiol to 30 µg appears to retain contraceptive effectiveness, but it is not yet known whether this decrease will reduce the risk of thrombosis or of the other side effects. - 79-0039 **Endometrial Response to Different Estrogens.** (Eng) Myhre, E. (Inst. Pathology, Rikshospitalet, Univ. Oslo, Oslo 1, Norway). In: *Front Horm Res* 5: 126-144; 1978.

Information concerning endometrial response to estrogen therapy, particularly in perimenopausal and postmenopausal women, is reviewed, and the author's experiences with endometrial bleeding and cystic glandular hyperplasia are contributed. There are two general criticisms of several previous studies: the dosage, mode of administration, and particularly the estrogenic preparation itself have not received sufficient attention. Furthermore, endometrial cancer has often been identified after relatively short courses of estrogen therapy (eg, 6 mo), while the latent period has often been of very short duration. This evidence appears to run contrary to the generally observed course of cancer induction, in which latent periods are often decades in length. It is suggested that what has actually occurred in these cases is an identification of existing neoplasms. Estrogen therapy has often been implicated as a source of post-menopausal bleeding. Of 259 patients followed 1-3.5 yr after treatment with estriol (213 patients; 2-4 mg/day) or estradiol (46 patients; same dose) by a regimen of 3 wk on treatment and 3 days off treatment, only 7 patients experienced slight bleeding (3 from the estriol group). No bleeding occurred when estriol treatment was ≤2 mg, or estradiol treatment was 1 mg. Cystic glandular hyperplasia, generally considered to be caused by estrogens from various sources, was studied in 204 patients over the age of 45 yr. There was a very high incidence of cases in the group age 48-56 yr. The gynecologists of these patients were interrogated by questionnaire, which revealed that only 14 patients (6.9%) had received previous estrogen therapy. It is advised, however, that women with already high blood-estrogen levels

should not be treated with endometrium-proliferating estrogenic substances. (72 refs)

- 79-0040 **Estrogens and Endometrial Carcinoma. Opinion on Drug Commission Findings.** (Ger) Lauritzen, C. (Univ.-Frauenklinik, Prittwitzstrasse 43, 7900 Ulm, W. Germany). *Fortschr Med* 96(45): 2293-2294; 1978.

Estrogens are currently believed to be facultative cocarcinogens rather than direct carcinogens. They increase the risk of endometrial cancer under certain circumstances; ie, long-term, acyclic treatment with high doses without gestagens. (18 refs)

- 79-0041 **Do Oral Contraceptives Induce Myoma?** (Ger) Eder, M. (Pathologisches Institut der Universität, Thalkirchner Strasse 36, D-8000, Munich 2, W. Germany); Prechtel, K. *Munch Med Wochenschr* 120(5): 1662; 1978.

Estrogen treatment and the use of estrogen-containing oral contraceptives cause hypertrophy of the myometrium. It is impossible to establish a correlation between uterine myoma and the use of estrogen preparations on the basis of autopsy series. (no refs)

- 79-0042 **Estrogen Therapy in the Young. Treatment of Turner's Syndrome with Estrogen.** (Eng) Levine, L. S. (Dept. Pediatrics, Div. Pediatric Oncology, Cornell Univ. Medical Coll., New York, NY, 10021). *Pediatrics* 62(6, part 2, Suppl): 1178-1183; 1978.

The use of estrogens in the treatment of Turner's syndrome is reviewed. Estrogen therapy in gonadal dysgenesis (GD) patients is likely to provoke endometrial hyperplasia, with the possible risk of subsequent development of endometrial carcinoma (EC). Data on the 10 literature cases of EC following estrogen therapy of GD patients are tabulated. In Turner's syndrome, there may be an increased susceptibility or genetic predisposition to EC development with estrogen treatment. (35 refs)

- 79-0043 **Effect of Prenatal Estrogen Exposure on Male Genitalia.** (Eng) Mills, J. L. (Dept. Pediatrics, Univ. Pennsylvania Sch. Medicine, Philadelphia, PA, 19104); Bongiovanni, A. M. *Pediatrics* 62(6, part 2, Suppl): 1160-1165; 1978.

Evidence of a relationship between maternal exposure to estrogen [particularly diethylstilbestrol (DES)] during pregnancy and later abnormal development of the urogenital sys-

tem of male offspring is reviewed. In one representative animal study, 15/24 male offspring suffered a variety of testicular changes: retention of one testis in the abdomen; epididymal cysts; hypoplastic, atrophic, and often calcified testes; inflammation of the seminal vesicles; nodules of the coagulating glands; and sterility. Repeated human studies have failed to uncover any relationship between prenatal estrogen exposure and male carcinoma, but a massive study of 50,282 pregnancies determined that there was an increased relative risk of birth defect development after DES exposure (1.56) and after ethinyl estradiol exposure (1.89). Specific malformations related to these exposures included hypospadias, eye and ear malformations, and Down's syndrome, but the numbers were too small to be statistically significant. Four case reports of congenital ambiguity following estrogen exposure in utero are summarized, in which the external genitalia ranged from normal female to male with hypogonadism. Abnormal testes were a common feature. In a case-control study of 163 men exposed to DES during fetal life, significant numbers of epididymal cysts, hypotrophic testes, hypoplastic penis and severely pathologic semen (Eliasson scale) occurred in the cases. Furthermore, significantly fewer cases had ejaculate volumes of 1.5 ml or more. There was no correlation between abnormal semen quality or genital anomalies and dose or time of commencement of DES therapy. The question still remains as to whether these exposed men will develop new or different types of abnormalities as they age. (36 refs)

- 79-0044 Experimental Colon Cancer.** (Eng) LaMont, J. T. (Div. Gastroenterology, Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA, 02115); O'Gorman, T. A. *Gastroenterology* 75(6): 1157-1169; 1978.

Information regarding the chemistry, metabolism, and mechanism of action of the more widely used colon carcinogens and the biology of the tumors they produce is reviewed. Several potent and specific chemical carcinogens produce in laboratory rodents a very accurate animal model of human colon cancer. Colon cancers have been produced with cholanthrenes, aromatic amines, hydrazine derivatives, alkylnitrosamides, and aflatoxin. The most potent and specific agent is 1,2-dimethylhydrazine (DMH). DMH undergoes metabolic activation in the host to the active carcinogen methyl-diazonium, an alkylating agent. This activation does not require intestinal flora, because DMH-treated germ-free animals also develop colonic tumors. The activated carcinogen reaches the colon by the blood stream or the fecal stream, and its primary effect in the colonic epithelial cell is methylation of DNA. The effect is not specific for the colon, because it also occurs in the liver and kidney, which are not target organs for DMH. After several days of reduced DNA synthesis, there is an increase in cellular proliferation and a widening of the proliferative zone. After 2-3 mo of treatment, there is a decrease in goblet cells, hyperplasia of the glands, and areas of focal atypia. Microscopic adenocarcinomas and adenomatous polyps appear after 4-6 mo, and they eventually produce rectal bleeding or bowel obstruction. Tumor yield

is affected by alteration in dietary fat, administration of bile salts and cholestyramine, and nonspecific colonic injury. The mechanism of these interactions is not known. The antigenic properties of colon cancers and the host-immune defenses directed against these tumors are strikingly similar in animals and humans. Although caution must be exercised in extrapolating the results of animal studies to human disease, animal models will hopefully expand the knowledge of a fundamental biology of colonic neoplasia. - 79-0045 Carcinogenic Natural Products.** (Eng) Weisburger, E. K. (NCI, Bethesda, MD). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 184-192; 1978.

A review is presented of carcinogenic compounds occurring naturally in plants and fungi. Studies have shown tobacco to contain nitrosamines, hydrazine, vinyl chloride, benz(a)pyrene, and polycyclic aromatic hydrocarbons, all proven carcinogens. The nut of the cycad plant, sometimes used as a source of starch, may contain cycasin, which is known to induce carcinomas of the liver, kidney, and intestine in laboratory animals. The root of the Indian plant *Jammu calamus* was used as a flavoring for vermouth until it was discovered that β -asarone (85% of the flavoring material) caused intestinal tumors in rats, and a similar compound, estragole, from estragon and tarragon oil, was found to be hepatocarcinogenic in young male mice. Among fungal carcinogens, ethyl carbamate (urethane) has been shown to induce lung and liver tumors when administered to mice and newborn rats, respectively. Mycotoxins, particularly aflatoxin B₁ (and to a lesser extent B₂, G₁, and G₂) produced by the fungus *Aspergillus flavus* is an extremely potent carcinogen and readily contaminates many types of grains and oilseeds. Compounds produced by other fungi that have effects similar to aflatoxin B₁ include sterigmatocystin, elaiomyacin, griseofulvin, and streptozotocin. It is postulated that many other naturally occurring carcinogens are present in the environment, but these are generally thought to be weak or adequately defended against by normal detoxification mechanisms, repair enzymes, and natural protective substances in foods (eg, indole derivatives in vegetables). A review is presented of current data on the incidence of various toxic substances in food products. In addition to pesticide residues, antibiotics, heavy metals, and hormones, various food products (especially smoked pork sausage) were found to contain hazardous levels of carcinogenic nitrosamines (up to 3.3 $\mu\text{g/kg}$). (58 refs)

- 79-0048 Carcinogenic N-Nitrosamines in Food Products.** (Rus) Kostiukskii, Ia. L. (Inst. Nutrition, Moscow, USSR); Arkhipov, G. N.; Malamed, D. B.; Zhukova, G. F. *Zh Vses Khim O-Va DI Mendeleeieva* 23(4): 406-410; 1978.

A review is presented summarizing current data on the incidence of various carcinogenic N-nitrosamines (NA) in food products. Depending on the method of analysis, the content of NA in meat samples ranged from 0.5 to 23.9 $\mu\text{g/kg}$. NA were detected in various fish products: the max content of NA was recorded in fish flour (2,000 $\mu\text{g/kg}$). (53 refs)

- 79-0049 Structure-Activity Studies on N-Nitroso Compounds and Their Precursors.** (Eng) Mirvish, S. S. (Eppley Inst. Res. Cancer, Omaha, NB, 68102). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 158-162; 1978.

Current knowledge concerning the carcinogenicity of N-nitroso compounds is reviewed. Nitrosamines are formed from a reaction of nitrous acid with a secondary amine or a simple amide. Nitrous acid is formed from environmental nitrates via nitrites, and when amines are involved, the reactive species is N_2O_3 , formed from two molecules of nitrous acid. Therefore, the rate of nitrosamine production is proportional to the square of the nitrous acid concentration, and directly proportional to the amine concentration. Although there is a "stoichiometric" rate constant for this reaction, the "true" rate constant (k_2) is based only on non-ionized amine

and is therefore pH dependent. The relationship between $\log k_2$ and the pK_a of the amine is approx linear, and the optimum pH is known to be 3.4. The success of H_2NO_2 + attack on amides is dependent upon the charge of the amides' nitrogen atoms: the stronger the negative charge, the quicker the reaction. Tertiary amines can also yield nitrosamines and guanidines can form nitrosoarea, but the reactions are slow. Morpholine, piperazine, and methyl aniline fed to Swiss and Strain A mice for 20 wk while NaNO_2 was administered in drinking water induced adenomas in a manner consistent with the kinetics discussed above, while nitrite levels of 0.25 g/l produced no adenomas. Nitrosamine carcinogenicity as related to the air/water partition coefficient (K_1) and ether/water partition coefficient (K_2) of each compound was studied; as K_1 and K_2 increased within a class of nitrosamines, esophageal carcinogenicity increased while liver carcinogenicity decreased. (14 refs)

- 79-0050 Chemical Structure and Carcinogenesis of Nitrosamines.** (Eng) Lijinsky, W. (Frederick Cancer Res. Center, Frederick, MD, 21501). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 148-157; 1978.

Studies of structure-activity relations in nitrosamines (NA's) are reviewed. Deuteration of dimethylnitrosamine or nitrosomorpholine and replacement of the α hydrogens of diethylnitrosamine or nitrosopyrrolidine by a methyl group results in appreciably lessened carcinogenic potency, consistent with the idea that rupture of an α -carbon-hydrogen bond is the limiting step in carcinogenesis by these compounds. Likewise, methylation of nitrosopiperidine (NP) at the 3- and 2-methyl positions results in progressively weakened carcinogenicity; the 2,6-dimethyl and 2,2,6,6-tetramethyl derivatives are noncarcinogenic. Of the dinitrosopiperazine derivatives, however, the parent compound, with no methyl groups, is the least potent and the 2,6-dimethyl derivative is the most potent, possibly due to the ability of the methyl groups to fix molecular conformation. The target organ of some NP's can be changed by replacing hydrogen in the 4-position with oxygen. The double bond also changes the organ specificity of certain compounds. Substituting chlorine atoms for hydrogen in NP greatly increases carcinogenicity. The findings raise the possibility that reactions related to hepatic carcinogenesis are not representative of the process in general. In any case, the α -hydrogens are not the rate-limiting step in all NA carcinogenesis. Studies in which the deuteration site was varied in a series of methylethylnitrosamines showed that oxidation at either carbon of the ethyl group and methylation were not related to carcinogenesis. The two 1-ethyl deuterated compounds produced liver tumors only, but the unsubstituted compound produced esophageal

phageal tumors as well. Thus, reactions leading to esophageal and liver carcinogenesis seem to be distinct. (28 refs)

- 79-0051 Nitrosamines in Animal Food (Letter to Editor).** (Eng) Lijinsky, W. (Frederick Cancer Res. Center, Frederick, MD, 21501). *Science* 202(4372): 1034; 1978.

A previously published briefing concerning the detection of nitrosamines in laboratory animal diets is discussed. The 50 ppb of nitrosodimethylamine (NDMA) found in the animal diets present no measurable risk to these animals, as they live only 2-3 yr; previous studies in rats fed higher concentrations of NDMA for a lifetime showed no carcinogenic effect, and there is little evidence of a synergistic effect of nitrosamines in carcinogenesis. While 50 ppb of NDMA might be significant if present in human food consumed for as long as 70 yr, its presence in the diets of experimental animals could have no bearing on the outcome of any experiment. (2 refs)

- 79-0052 On the Desirability of the Health Physics Society Assuming Responsibilities in Nonnuclear and Nonradiation Fields.** (Eng) Gammage, R. B. (Health and Safety Res. Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Thorngate, J. H.; Parkinson, W. W.; Hawthorne, A. R.; Vo-Dinh, T. *Health Phys* 35(5): 711-714; 1978.

The energy crisis places new demands on the Health Physics Society to expand its traditional and almost exclusive interest in ionizing radiation to embrace new energy system pollutants, particularly the chemical carcinogens. (12 refs)

- 79-0053 Common Sense and Environmental Pathology.** (Eng) Wagner, B. M. (No affiliation given). *Hum Pathol* 9(6): 733-734; 1978.

There is not yet unanimity within the scientific community regarding the extrapolation from laboratory animals to humans. The cause and effect relationship between cancer in humans and exposure to environmental chemicals is far too complex and too important to be determined on the basis of limited information. (3 refs)

- 79-0054 Lead Poisoning by Automobile Traffic.** (Ger) Blumer, W. (FMH Allgemeine Medizin, Ch-8754 Netstal, Switzerland). *Therapiewoche* 28(44): 8469-8470; 1978.

Evidence of a higher incidence of cancer in persons exposed to lead from automobile exhaust (AEX) (traffic police, inhabitants of high-traffic areas who also work on the street) is reviewed. This effect of AEX can be prevented by treat-

ment with Ca-EDTA; cancer mortality was 2% among 47 persons exposed to AEX who were treated with Ca-EDTA, compared with 13% among 185 exposed persons who were not treated. (15 refs)

- 79-0055 OSHA Issues New Arsenic Standard.** (Eng) Weinstein, G. L. (OSHA Office Carcinogen Standards). *Job Safety and Health Magazine* 6(7): 15-23; 1978.

Accumulated evidence has demonstrated that workers exposed to inorganic arsenic have been dying of lung cancer at 2-3 times the expected rate. The Occupational Safety and Health Administration has issued a final standard that establishes a permissible exposure limit of 10 $\mu\text{g}/\text{m}^3$ of air averaged over an 8-hr period. (no refs)

- 79-0056 Laws of Statistics Ignored by Statisticians (Letter to Editor).** (Eng) Cohen, B. L. (Dept. Physics, Univ. Pittsburg, Pittsburg, PA, 15260). *Health Phys* 35(4): 582-584; 1978.

A previous report on cancer mortality among workers at the Hanford plant ignored two basic laws of statistics: (1) given various statistical analyses for determining a result, one must not be influenced by the result in choosing which analysis to use; and (2) in the course of a series of statistical analyses, the stages at which results are reported must not be influenced by the results. In the Hanford report, a series of analyses were conducted, but only the one that gave a positive result was reported. (6 refs)

- 79-0057 Carcinogenic Possibilities in Foundry Operations.** (Eng) Scott, W. D. (Atlas Foundry and Machine Co., Tacoma, WA). *Foundry* 106(12): 48-55; 1978.

There is preliminary evidence that the incidence of lung cancer in a foundry is greater than that for the general public. The technology to measure potential carcinogens at trace levels is being developed. Among the proven carcinogens that will be found in some foundries are benzene, asbestos, arsenic, beryllium, and benzo(a)pyrene. (25 refs)

- 79-0058 DNA Repair and Its Coupling to DNA Replication in Eukaryotic Cells.** (Eng) Cleaver, J. E. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143). *Biochim Biophys Acta* 516(4): 489-516; 1978.

The three major systems for DNA repair (photoreactivation, excision repair, and postreplication repair) are reviewed. Photoreactivation appears to be vestigial. Mammalian cells have one major repair system, excision repair, with many branches (nucleotide excision repair, base excision repair,

REVIEW

crosslink repair, etc) and a multiplicity of enzymes. Any particular carcinogen produces a spectrum of damaged sites, and each kind of damage may be repaired by one or more branches of excision repair. In various genetic or physiologically normal or abnormal states, these different branches may have different relative importance. Excision repair is rarely complete, except at very low doses, and eukaryotic cells survive and replicate DNA despite the presence of unrepaired damage. When investigating repair and replication in various diseases, it is important to realize that these systems interact. Many alterations in replication in damaged cells may be secondary consequences of excision repair. Similarly, increases in sensitivity to radiation or carcinogens in many diseases may represent secondary consequences of other defects that alter DNA replication and its coupling with repair. (184 refs)

- 79-0059** Influence of Environmental Factors Excluding Ultra Violet Radiation on the Incidence of Skin Cancer. (Eng) Everall, J. D. (Skin Dept., Royal Marsden Hosp., London SW3, England); Dowd, P. M. *Bull Cancer (Paris)* 65(3): 271-279; 1978.

The recognized environmental causes (except UV radiation) of skin cancer (SC) are reviewed. Although SC is the most common form of cancer in the United States, accurate incidence rates are rarely available, because SC is very often curable and only infrequently results in death. Three principal groups of physical and chemical agents are known to cause SC: polycyclic aromatic hydrocarbons (PAH) inorganic arsenic, and radiation. PAH carcinogenesis occurs in areas of skin that are in contact with these carcinogens, usually of the benzopyrene and benzantracene families, which are products of the combustion and distillation of carbonaceous materials. The scrotum seems particularly susceptible. Previous studies have shown an increased risk of scrotal cancer in cotton mule spinners (62/1,000 men versus 1.8/1,000 men in other occupations) and in wax pressmen, employed ≥ 10 yr (806/100,000 population versus 0.15/100,000 in the general population). Pitchworkers had an 11-fold increased incidence of cutaneous squamous cell carcinoma. Whereas mortality in England and Wales from scrotal cancer is declining overall, the incidence of scrotal epithelioma continues to rise in the Birmingham area, being four times the expected value. Inorganic arsenic can be carcinogenic at any site following its inhalation and ingestion. Although documented cases are scarce, outbreaks of arsenical cancer following water supply contamination or pesticide use have occurred, resulting in an excess incidence of skin cancer. Ionizing radiation produces chiefly basal cell and squamous cell carcinomas at the sites of exposure. The average dose required to induce cancer appears to be approx 3,000 rems, and many fractionated doses over a long period are more harmful than a few large doses over a short time. (5 refs)

- 79-0060** Infrared Radiation as a Carcinogenic Agent (Letter to Editor). (Eng) Schwartz, R. A. (Ros-

well Park Memorial Inst., Buffalo, NY, 14263). *Br J Dermatol* 99(4): 460-461; 1978.

The role of infrared (IR) radiation in electromagnetic wave-induced carcinogenesis is discussed. Since most studies concerning radiation-induced skin cancer have involved the UV spectrum, there is a deficit of work involving the spectrum of 700-1,000,000 nanometers. At least one study has suggested that IR radiation is implicated in erythema ab igne and that IR may penetrate the epidermis and dermis. Since erythema ab igne predisposes to skin cancer, further studies of the relationship between IR irradiation and carcinogenesis are warranted. (11 refs)

- 79-0061** Increased Sensitivity of Xeroderma Pigmentosum Skin Fibroblasts to Carcinogenic Compounds (Letter to Editor). (Eng) McCormick, J. J. (E. Lansing, MI); Maher, V. M. *Arch Dermatol* 114(11): 1716; 1978.

Xeroderma pigmentosum (XP) cells are more sensitive than normal cells to the induction of mutations by low doses of UV light and polycyclic aromatic hydrocarbons, a finding that may be causally related to the enhanced cancer-prone condition of XP patients. XP cells are also more sensitive to several other classes of carcinogens, including aromatic amides, 4-nitroquinoline 1-oxide, and aflatoxins. (3 refs)

- 79-0062** Xeroderma Pigmentosum; Heterogeneous Syndrome and Model for UV Carcinogenesis. (Eng) Jung, E. G. (Hautklinik der Stadtischen Krankenanstalten, Postfach 23, D-6800 Mannheim, W. Germany). *Bull Cancer (Paris)* 65(3): 315-321; 1978.

A review is presented of xeroderma pigmentosum, a rare autosomal recessive genetic disease characterized by sun sensitivity, pigment anomalies, and multiple cutaneous neoplasms. It is hypothesized that patients are susceptible to these neoplasms at least partly because of disease-caused abnormalities in the self-protecting mechanisms of excision repair, photoreactivation, postreplication repair, and gap filling repair, which are usually active after UV irradiation-induced DNA mutation. Gene frequency is about $2.5/10^6$ in the overall population, and the frequency of XP heterozygotes is 0.2% to 0.5%. Different genetic variants of XP, although phenotypically similar, are separate entities causing different effects on the repair systems. These phenotypic manifestations, which include blistering after sun exposure, melanotic precanceroses, multiple melanoma, actinic keratoses, and multiple skin malignancies in sun exposed areas, are graded in severity and maintain intrafamilial constancy. When the gradations in severity are considered with determination of the rate of DNA repair and with cell fusion studies, XP can be differentiated into six known complementation groups, including the De Sanctis-Cacchione syndrome and the XP-variant type. There is evidence that the number of sister

chromatid exchanges per metaphase in XP is increased after UV irradiation in vitro, which is good evidence that XP cells are prone to UV-induced mutations that possibly lead to the initiation of cancer. (25 refs)

79-0063 Human Disorders Showing Increased Sensitivity to the Induction of Genetic Damage. (Eng)

Arlett, C. F. (MRC Cell Mutation Unit, Univ. Sussex, Falmer, Brighton BN1 9QG, England). *Annu Rev Genet* 12(1): 95-115; 1978.

Disorders involving increased sensitivity to the induction of genetic damage or defects in the ability of cells to repair DNA damage are reviewed. Clinical descriptions of xeroderma pigmentosum (XP), ataxia telangiectasia (AT), Fanconi's anemia, Bloom's syndrome, and Cockayne's syndrome are presented, and cellular anomalies associated with these conditions are described. In addition, mutagen sensitivity among patients with these disorders, DNA repair, and mutagen sensitivity in other disorders (eg, Down's syndrome, progeria) are reviewed. In XP, defects in DNA repair result in elevated levels of UV-induced mutations. UV-induced mutations probably arise during replication of unexcised damage, so that the hypermutability of XP strains results either from more lesions being replicated (excision-defective XP) or from increased susceptibility to errors of the defective postreplication repair (XP variants). In the somatic mutation theory of carcinogenesis, this hypermutability will lead to an increase in the level of UV-induced skin cancers, a principal symptom of the disorder. Although the neurological abnormalities found in some XP patients clearly cannot be a consequence of UV irradiation, a correlation has been discovered between the sensitivity of different XP cells to UV and the occurrence of neurological abnormalities in the donors. Defects in DNA repair after treatment of AT cells with γ -rays and Fanconi cells with mitomycin C are not associated with hypermutability by these agents. There is therefore no ready explanation for the elevated incidence of cancer in these disorders in terms of increased mutation rates. The lymphoreticular tumors in AT patients are probably associated with defects in the immune system. Although molecular explanations for the cellular observations in AT and Fanconi's anemia are rapidly evolving, there is presently no obvious relationship between the different defects in DNA repair and most of the clinical symptoms. Although Bloom's syndrome has many features in common with those of Fanconi's anemia and AT, no defect in DNA repair has yet been discovered. Molecular and cellular studies have certain direct clinical applications, especially in that they provide the possibility of early and reliable diagnosis. (125 refs)

79-0064 Hazards of "Low Dose" Irradiation to the Head and Neck. (Eng) Kaplan, E. L. (Chicago, IL). *Curr Surg* 35(6): 371-372; 1978.

Information concerning the long-term effects of low-dose irradiation to the head and neck is summarized briefly. Significant numbers of benign and malignant thyroid and salivary gland tumors are being discovered in patients 20-30 yr after they had received doses of $\leq 1,500$ rads (even a dose as low as 6.5 rads) to the head and neck region. (no refs)

79-0065 Twenty Years of Virusogenetic Theory of Tumor Development. (Rus) Ageenko, A. I. (P. A. Hertsen Res. Oncological Inst., Moscow, USSR). *Vopr Onkol* 24(11): 106-116; 1978.

This review summarizes the results and discusses the outlooks of the viral theory of tumorigenesis. The central dogma of the oncogenic virus hypothesis (that the integration of a viral genome is essential for stable transformation) had been proven in numerous direct experiments with small DNA-containing oncornaviruses and on some of the herpesviruses. The hypothesis is a cornerstone of more general theories and concepts (virogene or provirus hypotheses). Application of the oncogenic virus theory to the mechanisms of neoplastic transformation revealed that the virions of the oncornaviruses contain the enzyme reverse transcriptase, proved the widespread occurrence of some oncornaviruses (C type) among vertebrates revealed the vertical transmission of oncornaviruses, showed the possibility of induction of endogenous viruses by various carcinogens and mutagens, and determined the gene sequence in virion RNA in certain avian and rodent oncornaviruses. 79-0066 DNA Polymerases of Normal and Neoplastic Mammalian Cells. (Eng) Sarngadharan, M. G. (Litton Bionetics, Inc., 7300 Pearl St., Bethesda, MD, 20014); Robert-Guroff, M.; Gallo, R. C. *Biochim Biophys Acta* 516(4): 419-487; 1978.

The properties and possible functions of the DNA polymerases identified in normal, malignant, and virus-infected cells are reviewed. Mammalian cells contain at least three distinct DNA polymerases: DNA polymerase α appears to be responsible for chromosomal DNA replication, and DNA polymerase β seems to be involved in DNA repair; the role of DNA polymerase γ is not well understood. A fourth DNA polymerase, mitochondrial DNA polymerase, may prove to be the same as DNA polymerase γ . Infection by certain viruses causes cells to express additional DNA polymerases that are remarkably specific and are extremely useful as markers to detect viral infection in cells. Fidelity, the most crucial aspect of DNA replication in vivo, is controlled in prokaryotic systems by choice of the complementary nucleotide and by a "proofreading" activity associated with the DNA polymerase. The proofreading activity is not possessed by mammalian cellular DNA polymerases. Certain DNA polymerases show a high error rate in DNA synthesis in vitro, and fidelity levels can be further reduced by certain mutagenic/carcino-

REVIEW

genic metal ions. The terminal deoxyribonucleotidyltransferase may also contribute to somatic mutation in eukaryotes. The use of long-established tissue culture cell lines to study cellular DNA polymerase may present problems associated with contamination, so it is preferable to use fresh tissues or short-term-cultured cells. The use of cells infected by small DNA viruses (ie, polyoma virus or simian virus 40) will be extremely useful for the study of DNA replication in mammalian cells. (512 refs)

- 79-0067 RNA Tumor Viruses.** (Ger) Bauer, G. (McArdle Lab. Cancer Res., Univ. Wisconsin, 450 N. Randall Ave., Madison, WI, 53706). *Naturwiss Rundsch* 31(11): 445-455; 1978.

The structure of RNA tumor viruses, viral genes, gene products, defective and nondefective sarcoma viruses, reverse transcriptase, provirus synthesis, and the replication cycle of RNA tumor viruses are described. The mechanism of virus-induced transformation is still unclear. (20 refs)

Studies of the role of antibodies and antigens in tumor growth and their implications for cancer immunotherapy are reviewed. (35 refs)

- 79-0071 Interactions in the Natural History of Aging and Carcinogenesis.** (Eng) Pitot, H. C. (Dept. Oncology, McArdle Lab. Cancer Res., Medical Sch., Univ. Wisconsin, Madison, WI, 53706). *Fed Proc* 37(14): 2841-2847; 1978.

Proposed relationships between the various aspects of carcinogenesis and the aging process are discussed. The three stages of carcinogenesis are tumor initiation, promotion, and progression. In cultured mammalian fibroblasts (especially human), the first stage of aging involves initiation of the primary culture; the second stage is a period of vigorous replication; and the third stage is a period of declining mitotic potential culminating in cell death. During the last phase, aging cells lose their ability to replicate, becoming arrested in G₁. Cells in this stage may not be easily transformed, since continuous cell division and DNA synthesis are essential for expression of the transformed state. This implication that tumor promotion becomes less efficient as the aging process continues suggests that the later stages of carcinogenesis are modified by intrinsic cellular changes as well as by hormonal, immunologic, and nutritional factors. - 79-0074 Chromosome Studies in Polycythemia Vera.** (Eng) Wurster-Hill, D. H. (Dept. Pathology, Dartmouth Medical Sch., Hanover, NH, 03755); McIntyre, O. R. *Virchows Arch Cell Pathol* 29(1/2): 39-44; 1978.

Polycythemia vera (PV) represents an apparent monoclonal stem cell proliferation with a frequent transition to full neoplastic transformation. Of untreated PV patients, up to 26% have some chromosome abnormalities in the marrow at the time of diagnosis, and 10%-15% have an abnormal cell line or clone. Both structural and numerical aberrations occur. Aneuploidy is the most common chromosome abnormality, however, with hyperdiploid clones occurring more frequently than hypodiploid clones. Chromosomes 1, 8, 9, and 20 are involved in a nonrandom pattern, and aberrations of the F group, at least of chromosome 20, are associated to some extent with diseases involving erythroid hyperplasia. Leukemia develops in a certain percentage of patients, regardless of the type of treatment they have received, but the relationship between the chromosome abnormalities and the develop-

ment of leukemia is still unclear. The abnormal clones that occur in PV are quite stable, and there is no indication that they correlate with a prognosis of leukemic transformation. (no refs)

79-0077 Tumors as Clonal Proliferation. (Eng) Nowell, P. C. (Dept. Pathology, Sch. Medicine, Univ. Pennsylvania, Philadelphia, PA, 19104). *Virchows Arch Cell Pathol* 29(1/2): 145-150; 1978.

A review is presented of the relationship of tumor biology to chromosome banding studies of human malignancies, and the clinically relevant implications involved. Cytogenetic studies disclose the fact that most tumors are clonal (unicellular in origin) and have karyotypic aberrations. These nonrandom alterations detected on chromosomes by banding studies seem to point out the sites where the genes important in neoplasia are situated. It is hypothesized that tumor development occurs as a result of genetic lability within the neoplastic clone that subsequently leads to the emergence of increasingly mutant subpopulations with more malignant traits. Within this theoretical framework, acute leukemia, chronic leukemia, and preleukemia can be viewed as differing only in the rate at which an aberrant clone is expanding, with progression to a more aggressive phase that reflects the emergence of a new predominant subpopulation as the result of an additional genetic change. (6 refs)

79-0078 Introduction to the Modern Classification of the Non-Hodgkin Malignant Lymphomas. (Fre) Heimann, R. (Service d'anatomie pathologique, Institut Jules Bordet, Centre des Tumeurs de l'Universite Libre de Bruxelles, Brussels, Belgium); Van den Heule, B. *Dermatologica* 157(6): 345-356; 1978.

Developments leading to the Lukes and Kiel classifications of non-Hodgkin's malignant lymphomas are reviewed. Both classifications are based on the discoveries of modern immunology and on the conclusion that lymphoma development occurs in two steps. There is first a block in lymphocyte

activation at a certain stage, after which the blocked clone becomes neoplastic and replaces the normal components of lymph nodes. The type of cells observed in various lymphomas therefore depends on the stage of arrest in lymphocyte transformation. Although the two classifications rely on marker techniques for the identification of T, B, and U (undefined) lymphocytes, the Kiel classification is based on a morphological approach and that of Lukes on a functional approach. These modern classifications should gradually replace the Rappaport classification, which predates the major developments of modern immunology. The Kiel nomenclature is described briefly. (12 refs)

79-0079 The Radiological Symptomatology of Primary Malignant Neoplasia of the Kidney. (Ita) Musumeci, R. (Istituto Nazionale Tumori, 1 via Venezian, I-20133 Milan, Italy); Botturi, M. *Radiol Med (Torino)* 64(6): 753-768; 1978.

The radiological symptoms of primary tumors of the kidney are reviewed. Renal cell carcinoma, accounting for 85% of all primary malignant tumors of the kidney, affects men and women in equal ratio, mostly in the sixth and seventh decades of life. Renal sarcoma is rare; it may originate from the capsule, parenchyma or cavity. Wilms' tumors account for about 6% of all renal tumors, and they are bilateral in about 10% of all cases. It affects boys and girls in equal ratio, usually during the third and fourth years of life. In an autopsy series, the incidence of malignant lymphoma of the kidney was 13% in lymphogranulomatosis, 33% in non-Hodgkin lymphoma, and 63% in lymphocytic lymphoma with bone marrow involvement. (48 refs)

79-0080 Radiological Study of Prostate Diseases. (Ita) Belli, I. (Servizio di Radiologia, Ospedale di Circolo di Varese, 57 Viale Borri, I-21100 Varese, Italy); Porro, R. C.; Del Favero, C.; Nascimbene, C.; Tenti, L. *Radiol Med (Torino)* 64(6): 769-784; 1978.

The radiological aspects of diseases of the prostate gland are reviewed. Prostatic carcinoma is fairly common; its incidence is higher than that of carcinoma of the stomach and colon. About 20% of old men are believed to have asymptomatic prostatic carcinoma. Contrary to prostatic hypertrophy, prostate carcinoma originates mostly from the posterointerior portion of the gland, and its proliferation is atypical. Two forms of prostatic carcinoma can be distinguished: (1) a fairly small neoplasia with early bone metastases, and (2) locally spreading carcinoma with progressive invasion of the urethra and urinary bladder. (36 refs)

79-0081 Diseases of the Paranasal Sinuses. Part 3: Tumors of the Paranasal Sinuses. (Ger) Draf, W.

REVIEW

(Hals-Nasen-Ohren-Klinik, Universitat Mainz, Langenbeckstrasse 1, 6500 Mainz, W. Germany). *Fortschr Med* 96(47/48): 2355-2358; 1978.

The clinical, therapeutic, and diagnostic aspects of tumors of the paranasal sinuses are reviewed. Benign and malignant tumors of the paranasal sinuses are rare tumors; carcinomas at these sites account for about 0.2% of all carcinomas, and for about 3% of all carcinomas of the upper respiratory and digestive tracts. Their incidence is twice as high in men as in women, and they are rare in persons under the age of 35 yr. The incidence of sarcomas and adenomas is highest among young patients, while squamous-epithelial carcinomas usually occur in the fifth and sixth decades of life. The benign tumors include papillomas, adenomas, and mixed tumors of the epithelium; glioma, meningioma, neurofibroma, neurilemmoma, ganglioma, ganglioneuroma, paraganglioma, nevus, fibroma, myxoma, hemangioma, lymphangioma, chondroma, and lipoma of the connective tissues; osteoma, exostoses, osteoid osteoma, giant-cell tumors and cysts of the bones; and epithelial cysts, ameloblastoma, myxoma, fibroma, dentinoma, cementoma, cementifying fibroma and mixed tumors of the odontogenic tissues. The semimalignant tumors include inverted papilloma and leukoplakia of the epithelium; chordoma, plasmacytoma, teratoma, tumors of Rathke's pouch, hemangioendothelioma, hemangiopericytoma, Kaposi's sarcoma and Hand-Schuller-Christian disease of the connective tissue; and fibrous diseases. The malignant tumors of the paranasal sinuses are basal-cell carcinoma, squamous-epithelial carcinoma, lymphoepithelial carcinoma, spindle-cell carcinoma and adenocarcinoma of the epithelium, and Wegener's granulomatosis, fibrosarcoma, rhabdomyosarcoma, hemangioendotheliosarcoma, malignant lymphoma, myxosarcoma, reticulosarcoma, chondrosarcoma and Ewing's sarcoma of the connective tissues. (no refs)

- 79-0082 Woringer-Kolopp Disease.** (Fre) Revuz, J. (Service de Dermatologie, Hopital Henri-Mondor, F-94010 Creteil, France); Touraine, R. *Dermatologica* 157(6): 377-385; 1978.

Studies on the phenomenology and nosology of Woringer-Kolopp disease are reviewed. Woringer-Kolopp disease is a rare skin disease, affecting almost exclusively men, at practically any age. The disease is characterized by erythematous, slightly infiltrated lesions with round islets of normal skin and disruption of the stratum spinosum by dense epidermal infiltrate. The lesion develops in intact skin without preexisting "parapsoriasis en plaques." There are no visceral or lymph node lesions. Two forms are distinguished: a benign localized or regional form and a malignant disseminated type. A similar disseminated lesion, appearing on erythematous patches that are clinically and histologically similar to "parapsoriasis en plaque," is considered an ex-

tremely epidermotropic variant of mycosis fungoides. The examination of a new case supports the theory that Woringer-Kolopp disease is a proliferation of Merkel's cells. (20 refs)

- 79-0083 Papanicolaou Smear, Colposcopy and Cervical Cancer Precursors.** (Eng) Coppleson, M. (Dept. Gynaecology and Obstetrics, King George V Memorial Hosp., 139 Macquarie St., Sydney, New South Wales 2000, Australia). *Med J Aust* 2(7): 305-307; 1978.

The management of cervical cancer precursors based on exfoliative cytology and histologic examination has a major deficiency in that a lesion remains unseen. Colposcopy enables its rapid visualization and makes it possible to correlate the intensity of atypical changes with the corresponding histological changes. With a good colposcopy service, punch biopsy becomes the main method of diagnosis. Current approaches to the management of preclinical invasive carcinoma, carcinoma in situ, and dysplasia are discussed. (18 refs)

- 79-0084 Cancers Arising from Chronic Wounds, or the Hazards of Disturbed Healing (Report of 33 Cases).** (Fre) Abbes, M. (Service de Chirurgie, Centre Antoine Lacassagne, 36, Voie Romaine, 06054 Nice Cedex, France); Barety, M. *Ann Chir Plast* 23(2): 80-85; 1978.

Thirty-three patients (21 men and 12 women) developed cancer from chronic wounds caused by trauma and other factors. Most patients were aged > 50 yr at the time of diagnosis. The chronic wounds included burns, infections, damage to nerves, mechanical trauma, and radiogenic lesions. The latent period ranged from 6 mo to 50 yr. The av latent period was 29 yr for burns, 25 yr for chronic infection, 25 yr for nerve damage, 17 yr for mechanical trauma, and 13 yr for radiogenic lesions. Squamous cell carcinoma was diagnosed in 18 patients, basal cell carcinoma in 13, and rhabdomyosarcoma and spindle-cell sarcoma in 1 each. Lymph node metastases were found in two patients. (32 refs)

- 79-0085 The Vascular Endothelium--Pathobiologic Significance. A Review.** (Eng) Thorgeirsson, G. (Inst. Pathology, Case Western Reserve Univ., Cleveland, OH, 44106); Robertson, A. L. *Am J Pathol* 93(3): 801-848; 1978.

Diseases in which physiopathologic alterations of endothelial tissue may play key roles, including inflammation, immune disorders, and vascular neoplasia and metastasis, are re-

viewed. Vascular endothelium can give rise to benign and malignant hemangioendotheliomas, but it more frequently assumes a role in the metastatic spread of other tumors. (271 refs)

- 79-0086 Cell Kinetics: Summary of Recent Findings in Studies of Gastrointestinal Disease in Man.** (Eng) Lipkin, M. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021). *J Environ Pathol and Toxicol* 2(1): 9-11; 1978.

Recent findings of studies of human gastrointestinal diseases are reviewed with respect to using cytokinetic measurements to identify individuals and population groups at risk. In several diseases associated with increased frequencies of neoplasia in the gastrointestinal tract, as well as in other organs of man, cells lose their ability to repress DNA synthesis before the development of invasive malignancy. Studies of carcinogenesis mechanisms in populations at high risk for colon cancer should include identification of the abnormal cellular and related characteristics that are present. (22 refs)

- 79-0087 Carcinogenesis due to Air Pollution.** (Ita) Tar-
sitani, G. (No affiliation given). *Nuovi Ann Ig
Microbiol* 28(5): 301-306; 1977.

A review of epidemiological studies shows that some indicate that there is a correlation between cancer and air pollution but others do not. Epidemiological studies in this area should be coordinated. (10 refs)

- 79-0088 Adipose Tissue and Aetiology of Breast Cancer (Letter to Editor).** (Eng) Petrakis, N. L. (Dept. Epidemiology and International Health, Univ. California, San Francisco, CA, 94143); Ernster, V. L. *Lancet* 2(8097): 1001; 1978.

The hypothesis that women with abundant breast adipose tissue are predisposed to the development of breast cancer is refuted. Following release from breast fat cells, carcinogens first reach the venules and lymphatics surrounding the fat cells and then enter the circulation. Upon recirculation to the breast, carcinogens could be taken up directly and secreted by the alveolar epithelial cells. There is no need to believe that an excess of breast fat would be more hazardous to breast epithelium than any other more distantly located fat deposits,

such as sc fat and the omentum, that store fat-soluble substances. (2 refs)

- 79-0089 Early Nutrition, Growth, Disease, and Human Longevity.** (Eng) Stini, W. A. (Dept. Anthropology, Univ. Arizona, Tucson, AZ, 85721). *Nutr and Cancer* 1(1): 31-39; 1978.

The size of the human body has increased in the last 100 yr, and maximization of growth may predispose the individual to certain degenerative conditions, including cancer. Animal experiments have shown that restricted feeding is correlated with increased longevity and reduced tumor incidence. Indications of similar effects of diet on cancer incidence in humans are given. On a statistical basis alone, a greater number of cells, associated with accelerated growth, may increase the probability of malignant transformation. Cancers of the breast and colon are more prevalent in well-nourished than in undernourished populations. Both height and wt are positively correlated with cancer incidence in postmenopausal women. Increased estrogen synthesis and storage in adipose tissue may be implicated in this correlation. Japanese immigrants to Hawaii experienced a rapid increase in bowel cancer incidence simultaneous with a substantial increase in av body size. Some investigators argue that increased beef consumption is the underlying cause, and others attribute the correlation to an overall increase in fat consumption. However, not all researchers are convinced that correlations between fat intake per se and colon and breast cancer are truly significant. The mechanisms by which dietary factors influence cancer incidence probably involve the immune system. One hypothesis is that early nutritional deprivation may keep the immune system "young" longer, permitting it to retain competence to react against neoplasms later in life. Nutritional deprivation may lower the likelihood of autoimmune reactions in later years. (74 refs)

- 79-0090 Diet and Nutrition in Cancer Causation.** (Eng) Gori, G. B. (NCI, Bethesda, MD, 20014). *Nutr and Cancer* 1(1): 5-8; 1978.

Epidemiological and laboratory data on the relationship of dietary components to the incidence of certain forms of cancer are reviewed. Diet functions as an etiologic factor distinct from dietary contaminants and from genetic and environmental factors. Correlations between cancer incidence and dietary habits have been shown in studies of migrant populations, high- and low-cancer incidence populations, and special (ie, religious or ethnic) populations. (48 refs)

- 79-0091 The Role of Nutrition in the Control of Cancer.** (Eng) Navarro, M. D. (Univ. Santo Tomas Res. Center, Manila, Philippines). *Acta Manilana Series A* 17(27): 3-15; 1978.

The role of diet in carcinogenesis is discussed. It is suggested that persons who eat little or no meat, but consume large amounts of vegetables, fruits, and their seeds, are less subject to cancer. It is felt that the presence of fruits and vegetables rich in vitamin B17 and nitrilosides are responsible for this phenomenon. (19 refs)

- 79-0092 The Epidemiology of Endometrial Cancer.** (Eng) Kloppe, A. (Dept. Obstetrics and Gynecology, Univ. Aberdeen, Aberdeen, Scotland); Farr, V. In: *Front Horm Res* 5: 89-100; 1978.

A review of the epidemiology of endometrial cancer is presented that attributes the increase in endometrial cancer to the increasing use of estrogen replacement therapy in menopausal women. Risk factors include obesity, diabetes, and age. In the postmenopausal woman, estrogens are produced by the peripheral conversion in body fat of androstenedione to estrone. The more fat, the more estrone, and the more estrone, the greater the liability to cancer. One contradiction to this thesis is that estrogen administration acts independently of obesity in causing endometrial carcinoma. The association of diabetes with carcinoma of the endometrium is not as strong as that of obesity but it is probably real. Hypertension, affluence, and genetic factors have also been considered as risk factors but the evidence is not convincing. Examination of the role of endogenous estrogen in endometrial carcinoma implicates the action of estrogen unopposed by progesterone and possibly the prolonged action of estrogen but not the action of high estrogen levels. All evidence is against one endogenous estrogen, estrone. With regard to exogenous estrogens, the evidence points to estrone sulfate and conjugated equine estrogens, to synthetic estrogens such as stilbestrol or ethynyl estradiol or to nonsteroidal estrogens in the genesis of endometrial cancer. There is no evidence to implicate the natural steroids estradiol-17 β and estriol. (28 refs)

- 79-0093 Hodgkin's Disease.** (Eng) Izak, G. (Dept. Hematology, Hadassah Univ. Hosp. and Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel). *Isr J Med Sci* 14(10): 1010-1013; 1978.

The impaired cellular immunity of patients with Hodgkin's Disease (HD) and its possible relationship to the etiology of the disease and to the susceptibility of the patients to infections are reviewed. A viral infection could be partly responsi-

ble for the T-cell defect in HD patients, but no meaningful conclusions can be drawn from the available data. The prevalence of herpes zoster in HD exceeds substantially that observed in non-Hodgkin's lymphoma and in other conditions associated with impaired immune defense mechanisms. (37 refs)

- 79-0094 Disentangling Kaposi's Sarcoma (Letter to Editor).** (Eng) Hutt, M. S. (Geographical Pathology Unit, Dept. Morbid Anatomy, St. Thomas's Hosp. Medical Sch., London SE1, England); Bland, J. M. *Br Med J* 2(6150): 1498; 1978.

According to a series of papers from Malawi, Uganda, Tanzania, and Zambia, in which the distribution and clinical features of Kaposi's sarcoma were reviewed, there is no evidence to suggest that the tumor is related to the endemicity of malaria or to any other specific parasitic disease. It is likely that endogenous, possibly hormonal, factors play an increasing role with age in determining susceptibility or resistance to the causative agents. (4 refs)

- 79-0095 Membrane Changes During Neoplastic Transformation.** (Eng) Franke, W. W. (Inst. Experimental Pathology, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280 6900 Heidelberg, W. Germany). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a Meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 181-195; 1977.

Many recent studies have focused on delineating structural and biochemical abnormalities in membranes of transformed or malignant cells. It is now generally accepted that the unit membrane structure of a malignant cell cannot be distinguished from its counterpart in a normal cell. Attempts to prove that malignant cells exhibit differences in characteristics such as intercellular coupling (gap junctions, tight junctions), lipid composition, and microviscosity have at best been inconsistent. Convincing evidence has accumulated, however, to substantiate a correlation between malignancy and two biochemical alterations in cell membranes; (1) changes in the glycolipid pattern and in the activities of the corresponding glycosyltransferases and (2) increases in the sialic acid content of some fucose-containing glycopeptides. These changes appear to be widespread and consistent and, for this reason, may be regarded as general phenomena associated with neoplasia. (55 refs)

CHEMICAL CARCINOGENESIS

79-0096 A Quantitative Approach to Structure Activity Correlation in Chemical Mutagenesis-Preliminary Studies in the Ames' *Salmonella*/Microsome Assay Systems. (Eng) Johnson, H. L. (SRI International, Menlo Park, CA, 94025); Sigman, C. C. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 105-111; 1978.

A system for the quantitative analysis of the effects of chemical structure, properties, and reactivity on chemical mutagenesis is described together with its applications in predicting the mutagenicity of untested compounds. A computer model is derived whereby mutagenic activity is mathematically related to a combination of various chemical parameters (chemical composition, size, shape, reactivity, etc) and values that reflect the contribution of the associated parameter to activity. The system used for determination of activity involves the induction of revertants in the Ames *Salmonella typhimurium* histidine auxotroph assay. Activity is expressed as the concentration at which half-max activity is observed, and the ratio of the activity of the experimental compound to that of a chemical standard tested in the same study. After parameters and activities are chosen, the computer system PROPHET runs multiple regression analyses. The potential predictive value of the system is illustrated by the results of a preliminary Ames test with a group of aromatic amines. (6 refs)

79-0097 Ab Initio and Nonempirical MODPOT/VRDDO Calculations on Drugs, Carcinogens, Suspected Teratogens, and Biomolecules. (Eng) Kaufman, J. J. (Dept. Anesthesiology, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD, 21205); Popkie, H. E.; Preston, H. J. *Int J Quant Chem Quant Biol Symp* (5): 201-218; 1978.

An overview of recent nonempirical ab initio MODPOT/VRDDO calculations on a variety of drugs, nucleic acid constituents, normal neurotransmitters and their metabolites, carcinogens and their activated metabolites, suspected teratogens, and the attack of carcinogens on DNA constituents is presented. The intrinsic tractability and timing of the calculations as a function of the size and geometry of a variety of biomolecules is emphasized. The MODPOT/VRDDO method incorporates two desirable options into fast ab initio Gaussian programs: MODPOT-ab initio effective core model potentials and a charge-conserving integral prescreen-

ing approximation, which was named VRDDO (variable retention of diatomic differential overlap). For orbital energies and population analyses, the MODPOT/VRDDO results agree to essentially three decimal places with those of completely ab initio calculations with the same valence atomic basis set. Some molecular electrostatic potential contour maps, which were generated from previously calculated ab initio wave functions, are discussed. These maps allow a cogent comparison of pharmacophores in molecules that exert a similar pharmacological effect by the same mechanism. An example of such a comparison is that of morphine and nalorphine. (45 refs)

79-0098 Conformational Analysis in QSAR Investigations. (Eng) Hopfinger, A. J. (Case Western Reserve Univ., Cleveland, OH). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 74-81; 1978.

An attempt was made to correlate the biological activities and molecular features of a series of compounds using an automated quantitative structure-activity relationship (QSAR) method developed from two existing methods. The additive molecular thermodynamic model (linear free energy model) and conformational analysis (molecular orbital theory) were merged through solvent-dependent empirical energy functions. Molecular energy calculations involved functions such as dispersion, electrostatic interactions, hydrogen bonding, valence bond interactions, solute-solvent interactions, and intrinsic torsional potential. The CAMSEQ computer system was used for the calculations. Potential anticancer agents, the Baker triazines, were studied by QSAR in an in vitro dihydrofolate reductase inhibition activity assay. The statistical wts of the triazines correlated with their in vitro inhibition activity. Newly developed QSAR techniques are being used that employ molecular structure calculations to construct models of interactions between carcinogens and DNA. It is hoped that further calculations will shed light on the sites of physical interaction with DNA and indicate whether the physical interactions lead to chemical interactions. (15 refs)

79-0099 Pattern Recognition Methods. (Eng) Jurs, P. C. (Pennsylvania State Univ., University Park, PA 16802). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administra-*

tion Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 88-94; 1978.

The evaluation of structure-activity relations (QSAR) through the use of pattern recognition and chemical structure information-handling techniques is described. QSAR information may be useful in predicting the classification of untested compounds, based on discriminant functions and classification of tested compounds. The foundation of the structure-activity study is the modular computer system "ADAPT". Analysis begins with molecular structure input modules that are designed around square matrices whose main diagonals code for atom types and off-diagonals for bond types. Next, descriptors (physicochemical or calculated: topological and geometrical) must be generated from internal storage. These descriptors cover parameters such as partition coefficients, lipophilicity, steric constants, atom and bond fragments, substructures, and sizes and shapes of molecules. Finally, pattern recognition uses this data to congregate compounds with common properties into "limited regions of space", mathematically separable on a linear decision surface. Although this system has not yet been used in mutagenesis or carcinogenesis studies, preliminary studies on compounds associated with olfactory toxicity detection demonstrated a predictive ability of 92%. (21 refs)

- 79-0100 Reticulum Cell Sarcomas as Sequelae of CO₂-Treatment of Normal Tissue.** (Eng) Goldsmith, A. E. (Natl. Cancer Cytology Center, Melville, NY); Ryan, G. F. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 971-987; 1977.

The effects of abnormal CO₂ concentrations on various tissues were determined by exposing skin, mammary gland, and lymph node tissue from BALB/c, CBA, or Swiss albino mice in vitro to 45% CO₂ in air and transplanting these tissues as isografts and autografts. The incidence of malignant lymphomas in all CO₂-treated graft recipients, even autograft recipients, was higher than the spontaneous incidence in that strain. Irrespective of pretransplantation treatment of the graft or tissue type grafted, all inbred (BALB/c and CBA) recipients of isografts had a high lymphoma incidence (20%-61%). The noninbred Swiss mice had a spontaneous incidence of 8% at age 5-13 mo; the incidence increased above this age. In contrast to the inbred strains and possibly due to their higher spontaneous incidence, the occurrence of lymphoma in the Swiss mice rose to 63%-88% in all graft recipients, irrespective of pretransplantation treatment, type of graft, or tissue type grafted. Only the CO₂-treated autograft recipients had a high lymphoma incidence in BALB/c mice (33%); grafts exposed to air alone elicited no lymphomas in

their hosts. The appearance in graft recipients of significant numbers of lesions associated with altered immunological status, particularly glomerular lesions and myocarditis, pointed to an involvement of immunological mechanisms in lymphoma formation. Increased lymphoid activity in T- and B-cell lines was observed in the spleens of lymphoma-bearing mice, contrasting sharply with the decrease in nodal activity. Findings in non-lymphoma-bearing controls were the reverse. An interrelationship appeared between T-cell hyperplasia and B-cell atrophy. The highest incidences of both occurred in the experimental spleens, the lowest in the nodes. However, moderate incidences of both occurred in control spleens and nodes. Autoimmune-type mechanisms in some tumor productions were suggested by the development of lymphomas following CO₂ exposure in utero and of pulmonary adenocarcinomas (33%) and lymphomas following direct introduction of gaseous CO₂ in the subphrenic area. The chronic abnormal accumulation of CO₂ in the tissues may so alter the microenvironment of cells as to cause the formation of abnormal immunogenic cells or other factors with carcinogenic properties. (31 refs)

- 79-0101 Cytogenetic Effects of Inhaled Ozone.** (Eng) Tice, R. R. (Medical Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Bender, M. A.; Ivett, J. L.; Drew, R. T. *Mutat Res* 58(2/3): 293-304; 1978.

Cultured lymphocytes from Chinese hamsters that had inhaled ozone were examined for chromosomal aberrations, sister-chromatid exchanges (SCE), and cell-replication rates. The hamsters were exposed to an av ozone concentration of 0.43 ppm for 5 hr, for a total of 2.15 ppm-hr. Female mice were exposed to 2.0 ppm for 6 hr, or 12 ppm-hr. Blood was obtained either immediately or 7 or 14 days after exposure. No increases in chromosome-type aberrations were observed at any sampling time. At later sampling times, there were increases in the levels of aberrations of the chromatid-type. No increase in the levels of any chromosomal aberration type was seen in parallel direct bone-marrow preparations. SCE levels and cell-replication rates, determined in both the Chinese hamster peripheral lymphocyte cultures and in bone-marrow samples from the treated mice, failed to show any ozone-induced changes. These results are in contrast to those of a previous study in which substantial frequencies of chromosome deletions, rings, and dicentric were reported in cultures of blood cells after ozone exposures of 1.5 ppm-hr. The increases seen in the number of chromatid-type aberrations are similar to those reported in cultures of blood samples obtained from human subjects one or more weeks after exposure to 5 ppm-hr ozone. These results indicate that inhalation of ozone at the levels to which populations are currently exposed, and for the times such levels persist, is unlikely to present an appreciable genetic hazard. (34 refs)

- 79-0102 Arsenic and Cancer: Effects of Joint Administration of Arsenite and Selenite on the Genesis**

of Mammary Adenocarcinoma in Inbred Female C₃H/St Mice. (Eng) Schrauzer, G. N. (Dept. Chemistry, Univ. California at San Diego, Revelle Coll., La Jolla, CA, 92093); White, D. A.; McGinness, J. E.; Schneider, C. J.; Bell, L. J. *Bioorg Chem* 9(3): 245-253; 1978.

The effects of low doses of arsenic (as arsenite: 2 ppm in drinking water) and/or selenium (as selenite: 2 ppm in drinking water) on the incidence of spontaneous mammary adenocarcinomas in female inbred C₃H/St mice was investigated. At 22 mo, the spontaneous tumor incidence in the four experimental groups (controls, As, As + Se, Se) was 12/30, 10/30, 18/30, and 5/30, indicating that As abolished the anticarcinogenic effect of Se. The age at tumor onset in the four groups was 4.5, 9, 8, and 16 mo, respectively. Arsenite increased the tumor growth rates significantly and raised the incidence of multiple tumors (17%, 40%, 28%, and 0%, respectively). The tumor growth rates in the As + Se group were also increased, but the incidence of multiple tumors was significantly lower than that in the As group. The latter finding demonstrates that Se diminished some of the deleterious effects of As. (20 refs)

79-0103 Light and Electron Microscope Studies of the Rat Digestive Tract Following Prolonged and Short-Term Ingestion of Chrysotile Asbestos. (Eng) Jacobs, R. (Dept. Biochemistry, Univ. Coll., Cardiff, Wales); Humphrys, J.; Dodgson, K. S.; Richards, R. J. *Br J Exp Pathol* 59: 443-453; 1978.

The effects of feeding MRC hooded rats 0.5 or 50 mg chrysotile asbestos daily for 1 wk or 14 mo on the cells of the gastrointestinal tract were determined by light and electron microscopy. Light microscopy showed that the ileum underwent the most marked changes. Short- or long-term feeding at either dose resulted in general disorganization of the ileum: the regularity of the tips of the villi was absent, and vacuolization in the mucosal epithelia and the connective tissue villus core of the lamina propria was marked. In some cases, the mucosal epithelial cells were separated from the villus core along the line of the thin basal lamina. The rectal and colonic lumens contained clumps of nuclei and blue-staining mucinous material, but the esophagus, stomach, and cecum had a basically normal appearance. Electron microscopy of the ileum of rats receiving 50 mg/kg asbestos for 14 mo confirmed the light microscope findings and showed various changes in the mucosal lining cells that were consistent with a mineral-induced cytotoxicity. Mucosal absorptive cells were detached along the line of the intercellular membranes, with loss of the tight junctional complexes, thus creating enlarged intercellular spaces. Loss of the brush border, vacuolization along intercellular membranes or in the cells themselves, and abnormal blebbing of the surface microvilli were also noted. Colonic tissue showed similar changes, and both microvilli and goblet cells stained very densely. The lumen was filled with mucinous cell debris and bacteria that adhered to the cell surface even after repeated washing. It appears that

chrysotile asbestos-induced toxicity is specific for certain regions of the rat gastrointestinal tract. (13 refs)

79-0104 Short-Term Asbestos Exposure and Delayed Cancer Risk. (Eng) Seidman, H. (American Cancer Society, 777 Third Ave., New York, NY, 10017); Lillis, R.; Selikoff, I. J. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 943-960; 1977.

Lung cancer mortality was examined in 914 white men who had worked for short periods (585 for <1 yr) in an amosite asbestos factory during World War II and who were followed for 30 yr, beginning in 1943. Mortality data for each of the 30 yr were compared with age-specific death rates for white men in New Jersey during 1941-1974. Of the 135 verified cancer deaths in the asbestos workers, 76 were due to lung cancer. Among the 65 men who worked <1 mo, no lung cancer death occurred until 25 yr postexposure. With longer asbestos exposure (ie., 2, 3, 6, mo), the cancer risk became greater; and in men who worked 2+ yr, the observed number of lung cancer deaths 10-29 yr after onset of work was 33 vs 4.00 expected. Lung cancer alone did not account for the excess mortality in the 2+ yr group, in which the number of deaths from all causes was 113 vs 73.45 expected and the number of deaths from all cancers was 47 vs 14.89 expected. It is emphasized that longer employment resulted in cancer after shorter postexposure observation. (17 refs)

79-0105 Malignant Mesothelioma of the Pleura in Barrow-in-Furness. (Eng) Edge, J. R. (North Lonsdale Hosp., Barrow-in-Furness, Cumbria LA14 2JD, England); Choudhury, S. L. *Thorax* 33(1): 26-30; 1978.

The occurrence of malignant pleural mesothelioma among 47 men and 3 women living in Barrow-in-Furness, England (a town in which ship construction is the major industry), is discussed. All cases were diagnosed between 1966 and 1976, and all patients but one were known to have been exposed to asbestos dust (all 47 men and 1 woman had worked in the shipyard; 1 woman was married to a shipyard plumber). The histological picture was predominantly mixed in 24 patients, tubopapillary in 15, and undifferentiated in 11. Asbestos fiber counts in the lungs exceeded acceptable levels for the general population in 18/20 patients examined, and 13/16 patients examined had asbestos bodies in the lungs. Electron microscopy showed that the predominant fiber was crocidolite and that the number of fibers present was always small compared with the usual number in pulmonary asbestosis. Forty-seven patients presented with a massive pleural effusion, and pleural plaques were diagnosed on the side opposite the tumor in 30 cases. Distal metastases were never recognized clinical-

ly, but were found in 25/47 patients at necropsy. Diagnostically, cytological examination of the pleural fluid was as useful as needle biopsy. (19 refs)

- 79-0106 Studies on Lead and Cadmium Contamination from Drying of Cereals by Gases from Burning Fuel.** (Ger) Woggon, H. (Zentralinstitut für Ernährung, Arthur-Scheunert-Allee 114/116, DDR-1505 Bergholz-Rehbrücke, E. Germany); Malkus, Z. *Nahrung* 22(7): 647-654; 1978.

Two methods for determination of Cd and Pb in cereals were used to study possible contamination if diesel oil or brown coal is used as the fuel for the drying of cereal. Direct drying using exhaust gas from burning fuel was found to add no significant amount of Cd or Pb to cereal; however, because earlier studies have shown increases in 3,4-benzpyrene and other polyaromatic compounds, it is recommended that this type of drying be abandoned. The av levels found after drying were: 0.052 mg Cd/kg (suggested tolerance 0.10 mg/kg) and 0.36 mg Pb/kg (suggested tolerance 0.5 mg/kg). Direct and indirect (no contact between cereal and exhaust gases from the burning fuel) drying gave similar results. Direct inverse polarography (IP) and indirect IP (extraction with dithizone and re-extraction with HCl) were used for determination of Pb and Cd. Direct IP was found preferable for small amounts of Cd and for all levels of Pb. Recoveries of known amounts of Cd or Pb ranged from 76%-133%. Both methods seem suitable for studies of Pb or Cd contents of cereal products. (6 refs)

- 79-0107 Chromosome Studies on Blood Lymphocytes of Men Occupationally Exposed to Cadmium.** (Eng) O'Riordan, M. L. (MRC Clinical, Population Cytogenetics Unit., Western General Hosp., Crewe Road, Edinburgh, Scotland); Hughes, E. G.; Evans, H. J. *Mutat Res* 58(2/3): 305-311; 1978.

Chromosome studies were carried out on peripheral blood lymphocytes from 40 men occupationally exposed to cadmium salts for periods up to 34 yr and from 13 on-site controls. The mean Cd blood level in the exposed group was 1.95 $\mu\text{g}/100\text{ ml}$ (range <0.2-14.0 $\mu\text{g}/100\text{ ml}$), whereas eight controls had levels <0.2 $\mu\text{g}/100\text{ ml}$ and the remaining five levels between 0.6 to 2.9 $\mu\text{g}/100\text{ ml}$. Although four chromatid interchanges were observed in 3,740 cells from the exposed workers and none in the 1,243 cells from controls, there was no significant difference in aberration frequency between the two groups. Three of the chromatid interchanges in the exposed workers involved both homologs of chromosome 9, and the fourth involved two F group (19-20) chromosomes. The extent of chromosome damage detected in an individual worker did not correlate with his length or degree of exposure to Cd or with his blood Cd level. Possible reasons for contrasting findings on the chromosome-damaging effects of

Cd in other published reports are discussed, and the possibility that heavy metals might act synergistically to enhance the mutagenicity of other compounds present in the environment is considered. (24 refs)

- 79-0108 Comparative Studies of Chromosomal Aberration and Mutagenicity of Trivalent and Hexavalent Chromium.** (Eng) Nakamuro, K. (Dept. Hygienic Chemistry and Microbiology, Natl. Inst. Hygienic Sciences, Kamiyoga, Setagaya-ku, Tokyo 158, Japan); Yoshikawa, K.; Sayato, Y.; Kurata, H. *Mutat Res* 58(2/3): 175-181; 1978.

The effects of two hexavalent and three trivalent chromium compounds on the incidence of chromosome aberrations in leukocytes from a healthy man on the results of a recombination assay (rec-assay) with wild-type *Bacillus subtilis* strain 17A and its recombination-deficient (rec-) derivative 45T, and on the results of a mutation assay for arginine reversion with *Escherichia coli* strain Hs30R were investigated. When leukocytes were exposed to concentrations of chromium compounds near natural levels, the frequency of aberrations, including chromosome breaks and exchanges, as well as the total number of aberrations both increased with increasing dose. In total yield of aberrations (on an equimolar basis) the efficiency in inducing chromosomal aberrations was $\text{K}_2\text{Cr}_2\text{O}_7 > \text{K}_2\text{CrO}_4 > \text{Cr}(\text{CH}_3\text{COO})_3 > \text{Cr}(\text{NO}_3)_3, \text{CrCl}_3$. Rec-assay effects were marked, as indicated by differences in the size of the inhibition zone from 2 to 9 mm. The hierarchy of DNA-damaging activity was similar to the efficiency of inducing chromosomal aberrations; $\text{K}_2\text{Cr}_2\text{O}_7$ and K_2CrO_4 were the most active and induced a dose-dependent effect. Three compounds exhibited mutagenic activity in the hierarchy $\text{K}_2\text{Cr}_2\text{O}_7 > \text{K}_2\text{CrO}_4 > \text{Cr}(\text{CH}_3\text{COO})_3$; cell survival was inversely related and frequency of reversion directly related to dose in each case. The two hexavalent chromium compounds were consistently more successful in producing aberrations than were the three trivalent compounds. The evidence supports the hypothesis that DNA damage induced as chromosomal aberrations is related to the rec-effect and mutagenicity. (13 refs)

- 79-0109 The Mutagenicity of Dichloroacetaldehyde.** (Eng) Lofroth, G. (Wallenberg Lab., Univ. Stockholm, S-106 91 Stockholm, Sweden). *Z Naturforsch C* 33(9/10): 783-785; 1978.

The Salmonella/microsome test showed that 2,2-dichloroacetaldehyde, a presumed metabolite of the insecticides dichlorvos and trichlorphon, was more mutagenic [58 revertants/micromole (μmol)] than the established mutagen dichlorvos [17 revertants/ μmol] but approx one-tenth as mutagenic as chloroacetaldehyde [515 revertants/ μmol]. (20 refs)

- 79-0110 On the Detection of Volatile Liquid Mutagens with Bacteria: Experiments with Dichlorvos and Epichlorhydrin.** (Eng) Bridges, B. A. (M.R.C. Cell Mutation Unit, Univ. Sussex, Falmer, Brighton BN1 9QG, England). *Mutat Res* 54(3): 367-371; 1978.

Optimal conditions for detecting volatile liquid mutagens by means of bacteria were studied using dichlorvos and epichlorhydrin. The bacteria were usually suspended for 1 hr in a solution of the mutagen in buffer then plated on a medium that would permit expression of induced mutants. The modified fluctuation medium helps ensure that the mutagen is present for as long as possible when the maximum number of cells are available for exposure. The possibility of loss of mutagen through evaporation was avoided by incorporation of a relatively stable mutagen into semi-enriched plates. In the case of dichlorvos the sensitivity was not as great when the mutagen was added to the agar as when the mutagen was allowed to vaporize from a filter paper pad or watch-glass in the jar. Sensitivity was further enhanced by using a plasmid-containing strain of *Escherichia coli* (such as CM 881) and by using glass rather than polystyrene plates. Thus detection of dichlorvos concentrations down to at least 0.1 µg/ml agar was possible. With epichlorhydrin, concentrations down to 1.25 µg/ml air were detectable using *Salmonella typhimurium* TA100 on the surface of agar in glass plates sealed in air-tight steel or glass jars. (8 refs)

- 79-0111 The Balkan Endemic Nephropathy and Cancer of the Urinary Tract.** (Eng) Markovic, B. (Medical Center, Gnjilane, Yugoslavia); Lebedev, S. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp; 1179-1189; 1977.

The development of malignant urothelial tumors in Balkan endemic nephropathy, a chronic kidney disease caused by drinking water containing silicate minerals and heavy blastogenic metals, was studied experimentally in mice. The animals were given 50 mg/liter quartz and 100 mg/liter quartzite in the drinking water. The quartzite contained Ni, Cr, Al, Mg, Ba, Fe, Ca, and Ti. After 2 mo, the animals lost wt and developed polydipsia and polyuria. Every fourth month, quartzite was discontinued during the first 15 days; during this time the water contained only quartz. During the next 15 days, the mice were given pure water only. Chronic interstitial nephritis and urinary tract tumors were found simultaneously after 12 mo. In the kidney, focal periglomerular inflammatory-proliferative infiltration led to fibrotic thickening of the Bowman's capsule. Sclerosis and hyalinization occurred in the glomeruli. The parenchymal lesions included dystrophy, hypertrophy, atrophy, or necrosis. Tubules were most often found to be dystrophic or hypertrophic in their proximal convoluted areas. Ultrastructural examination of

kidney samples taken at 9-12 mo showed focal mesenchymal proliferation of the interstice of the renal cortex and medulla with multiplication of collagen fibers. The glomerular changes were focal. Fine spherical granular osmiophilic inclusions, 0.1-0.5 µ in diameter, occurred in the mitochondria of the proximal tubular epithelium in all samples studied. Urothelial neoplastic proliferation occurred in over half the treated animals. (9 refs)

- 79-0112 Sister-Chromatid Exchange Induction by Sodium Selenite: Dependence on the Presence of Red Blood Cells or Red Blood Cell Lysate.** (Eng) Ray, J. H. (Graduate Sch. Biomedical Sciences, Medical Genetics Center, Univ. Texas Health Science Center, P. O. Box 20334, Astrodome Station, Houston, TX, 77025); Altenburg, L. C. *Mutat Res* 54(3): 343-354; 1978.

Induction of sister-chromatid exchange (SCE) by sodium selenite (Na_2SeO_3) was studied in short- and long-term cell cultures. Concentrations of Na_2SeO_3 (7.90×10^{-6} M and greater) that produced elevated SCE frequencies in whole-blood cultures did not increase SCE frequencies above control levels in Ficoll-Hypaque-purified lymphocyte cultures. However, whole blood and purified lymphocyte cultures were equally sensitive to SCE induction by methyl methanesulfonate, ethyl methanesulfonate, and N-hydroxy-2-acetylaminofluorene. Addition of RBC or RBC lysate, but not RBC ghosts, plus Na_2SeO_3 to purified lymphocyte cultures increased the SCE frequency to a value comparable to that observed in whole blood cultures exposed to the same Na_2SeO_3 concentration. Na_2SeO_3 alone did not increase the SCE frequency in xeroderma pigmentosum (XP12RO) or human lymphoblastoid cell cultures, whereas the SCE frequency in both cultures was significantly increased after treatment with Na_2SeO_3 plus RBC lysate. Na_2SeO_3 was equally toxic to the cultured cells in the presence and absence of RBC lysate. (39 refs)

- 79-0113 Oxidation of Inactive Trivalent Chromium to the Mutagenic Hexavalent Form.** (Eng) Petrilli, F. L. (Inst. Hygiene, Univ. Genoa, Via Pastore 1, 16132, Genoa, Italy); De Flora, S. *Mutat Res* 58(2/3): 167-173; 1978.

In plate-incorporation tests, soluble trivalent chromium compounds (chromium potassium sulfate, chromium nitrate, chromium chloride, neochromium and chromium alum) were inactive for *Salmonella typhimurium* TA100, even at milligram amounts per plate. No mutagenic effect could be detected in the absence or in the presence of rat liver, lung, or muscle microsomal fractions; rat muscle mitochondria (with or without ATP); oxidized glutathione; or human serum, plasma, or RBC lysates. Conversely, the addition of a strongly oxidizing agent (potassium permanganate) resulted in toxic effects in plates incorporating more than 40-80 µg of compounds and elicited a dose-effect mutagenic re-

sponse at 10-40 μg per plate. These effects could be ascribed to oxidation of chromium from the trivalent to the active hexavalent state. Insoluble chromite, assayed in the spot test, was spontaneously mutagenic, owing to contamination of the industrial product with hexavalent chromium. These results may be useful in interpreting the findings of carcinogenicity tests and in predicting the health hazards linked to chromium. (20 refs)

- 79-0114 Induction of Monozygotic Twinning in the Mouse.** (Eng) Kaufman, M. H. (Dept. Anatomy, Univ. Cambridge, Cambridge, England); O'Shea, K. S. *Nature* 276(5689): 707-708; 1978.

The teratogenicity of vincristine sulfate was investigated during the early stages of embryogenesis in CFLP mice. Mice were injected ip with 0.3 mg/kg vincristine sulfate on the 6th, 7th, or 8th day of gestation. A low incidence of gross anomalies (ie, a hindbrain appearing flattened, apparently caused by collapse of the region overlying the fourth ventricle) was observed in fetuses on days 10 and 12 of gestation. A high incidence of fetuses with abnormal heads was observed in the population of fetuses isolated from females treated on the 7th day (6.2%) compared with those isolated from females treated on the 6th (2.6%) and 8th (2.6%) day of gestation. Four sets of twins, one pair of which was conjoined, were observed when females were treated on the 7th day of pregnancy. Of five females autopsied on the 10th day, three each had one set of twins, and a single pair of conjoined twins (janiceps type) was isolated from one of four females autopsied on the 12th day of gestation. One additional set of twins was obtained from a female treated on the 8th day. The present study is unique in that an experimental method of inducing a low but significant incidence of identical twinning in a mammal is reported. (11 refs)

- 79-0115 Sister Chromatid Exchange: A Rapid Quantitative Measure of Genetic Injury.** (Eng) Carrano, A. V. (No affiliation given). *Energy Technol Rev* 1-8; 1978.

The phenomenon of sister chromatid exchange (SCE) is proposed as a means of rapidly screening potentially carcinogenic and mutagenic substances, establishing dose-response relationships, and assessing human exposure. SCE is known to increase when cells are exposed to carcinogens, but detection is now possible using bromodeoxyuridine (BrdUrd) incorporation into DNA for two cycles of replication; the distribution of BrdUrd-substituted DNA is the staining pattern with Hoechst dye 33258 or Giemsa stain, permitting the number of SCEs to be determined. When the rate of SCE was compared with the rate of mutation at the hypoxanthine phosphoribosyltransferase (hprt) locus after incubation of Chinese hamster cells with the mutagens ethyl methanesulfonate (EMS), ethylnitrosourea (ENU), mitomycin C, or proflavine sulfate for 18 hr. All four chemicals yielded linear

dose-response curves for both SCE and the mutations, but the slopes differed for each carcinogen. The relative hierarchy of the SCE-mutation ratio was mitomycin C > proflavine sulfonate > EMS > ENU. Rabbits were injected ip each wk with mitomycin C, benzo(a)pyrene, or methylcholanthrene for 8 weeks, and their blood lymphocytes were cultured and analyzed for SCE. Small increases in SCE occurred that, after the fourth injection, did not return to normal within 1 wk but increased fourfold after the 5th wk and were sustained at this level for 5 wk. At that time SCE decreased to 2x the control level and remained there >4 mo. Human studies have indicated that persons (including children in utero) exposed to probable mutagens (eg, chemotherapeutic drugs and organic solvents) have elevated lymphocyte SCE levels. The SCE assay should provide the means to assess the extent and nature of the genetic burden induced in humans by environmental chemicals. (13 refs)

- 79-0116 The Mutagenicity of Methyl Orange and Metabolites Produced by Intestinal Anaerobes.** (Eng) Chung, K. T. (Food Sciences Inst., Purdue Univ., West Lafayette, IN, 47907); Fulk, G. E.; Andrews, A. W. *Mutat Res* 58(2/3): 375-379; 1978.

The azo dye methyl orange and the products of its conversion by anaerobic gut bacteria were tested for mutagenicity in the Ames *Salmonella typhimurium* assay using strains TA98, TA100, TA1535, TA1537, and TA1538, with and without S-9 rat liver microsome mix present. After incubation of methyl orange with the *Bacteroides fragilis* subspecies *thetaiotaomicron* and with a *Fusobacterium* species 2 for 17-19 hr, culture filtrates were analyzed by thin-layer chromatography (TLC) and 0.25 ml was incubated in the Salmonella assay. Culture filtrates from both species incubated with S-9 mix were mutagenic (as indicated by reversion to prototrophy) in strains TA1538 and TA98. Sulfanilic acid, N,N-dimethyl-p-phenylenediamine (DMPD), and an unknown impurity were isolated from the filtrates by TLC in addition to the methyl orange. The isolated impure DMPD, a commercial DMPD, and a laboratory-synthesized DMPD, as well as the unknown impurity were all found to be mutagenic when tested with strain 1538, whereas the sulfanilic acid was not. Impure isolated DMPD and synthesized DMPD demonstrated mutagenicity in a dose-dependent manner in strain TA1538 with S-9 mix, although a toxic effect was noted when concentrations >100 μg were used. It is suggested that these metabolic products could be reabsorbed from the digestive tract and act adversely on other body tissues to form tumors. (15 refs)

- 79-0117 The Induction of Dominant Lethal Mutations in *Tilapia mossambica* by Alkane Sulphonic Esters.** (Eng) Hemsworth, B. N. (Life Science Lab., Teesside Polytechnic, Cleveland, England); Wardhaugh, A. A. *Mutat Res* 58(2/3): 263-268; 1978.

A serial mating system was used to study the effects of methyl methanesulfonate (MMS) and dimethylmyleran on the tropical freshwater fish, *Tilapia mossambica*. Male fish were given MMS (50 or 70 mg/kg ip) before introduction of females to the aquarium. Those females observed eventually to be carrying eggs were replaced within 24 hr of mating. About 60 hr after mating, eggs and embryos were removed from the mother and developing embryos examined by a low-power microscope for 1 wk. There was a significant incidence in gross anatomical deformity in embryos conceived during the 3 wk following paternal treatment with 50 mg/kg MMS. At the higher dose, 50% of the relatively few embryos produced in the 1st wk were defective. In subsequent weeks, 30% of embryos were defective. Paternal MMS treatment also reduced the number of embryos actually produced compared with that in controls. The isomeric forms of dimethylmyleran were also embryopathic. The meso isomer (4 mg/kg) caused the deformation of 44% of embryos produced in wk 1; the same dose of the \pm isomer affected 62% of embryos. The drug-induced embryopathies appear to be due generally to defects manifest initially during gastrulation and to be comparable to the defective embryos produced in *Xenopus laevis* by sperm treatment with mutagens. (11 refs)

79-0118 Enhancement of Repair Replication in Mammalian Cells by Hydroxyurea. (Eng) Clarkson, J. M. (Science Park-Res. Div., Univ. Texas System Cancer Center, Smithville, TX, 78957). *Mutat Res* 52(2): 273-284; 1978.

The effect of hydroxyurea (HU) on DNA repair replication was studied in Chinese hamster ovary (CHO) cells. Mitotic cells were treated with UV light, methyl methanesulfonate (MMS), or nitrogen mustard and incubated in the presence of one of the four ^3H -labeled deoxyribonucleosides plus bromodeoxyuridine and fluorodeoxyuridine for 2 hr in the presence or absence of 2 mM HU. The amount of repair replication was quantitated on CsCl gradients. The uptake of each nucleoside was increased twofold by the presence of HU during the incubation period. Following MMS treatment, pool sizes for each of the nucleosides were estimated by varying the amount of exogenously supplied nucleoside. In each case, pool size was insensitive to HU. These data are consistent with reports that HU has a detrimental effect on DNA repair. HU does not appear to inhibit repair synthesis, but rather increases it so that ligation is prevented, with the result that excision and resynthesis continue in an uncontrolled manner. (24 refs)

79-0119 Postnatal and Transplacental Carcinogenic Effects of Methylmethanesulfonate (MMS) and Ethylmethanesulfonate (EMS) in Hooded Rats. (Ger) Schneider, J. (Institut für Allgemeine Pathologie und Pathologische Anatomie, Medizinische Akademie Erfurt,

Nordhauser Strasse 74, DDR-50 Erfurt, E. Germany); Warzok, R.; Schreiber, D.; Heiderstadt, R. *Exp Pathol (Jena)* 16(1-6): 157-167; 1978.

The postnatal and transplacental carcinogenic effect of methyl methanesulfonate (MMS) and ethyl methanesulfonate (EMS) was studied in inbred strain E hooded rats. Twenty-eight juvenile rats (Group 1) received 15 iv injections of MMS (first injection 100 mg/kg, remainder 50 mg/kg) at 2-wk intervals. Seven pregnant rats received 30 mg/kg MMS iv on the 21st day of pregnancy; the carcinogenic action was studied in 38 offspring (Group 2). Twenty-eight juvenile rats (Group 3) received 13-15 iv injections of EMS (110 mg/kg) at 2-wk intervals. Seven pregnant rats received 100 mg/kg EMS iv on the 21st day of pregnancy; 32 offspring were studied (Group 4). The animals were examined upon sacrifice or spontaneous death at 167-684 days. The numbers of tumor-bearing animals were 18/28 in Group 1 (25 tumors), 12/38 in Group 2 (13 tumors), 24/28 in Group 3 (51 tumors), and 5/32 in Group 4 (7 tumors). The incidence of tumors of the CNS and nerves was 18/25 in Group 1, 8/13 in Group 2, 46/51 in Group 3, and 4/7 in Group 4. The neural tumors were identified as astrocytomas, oligodendrogliomas, malignant neurinomas, and multicentric sarcomas; the extraneural tumors comprised sarcomas, carcinomas, malignant lymphomas, stem-cell leukemia, and chronic myelosis. Three neurogenic tumors and one case of chronic myelosis were found in 4/14 mothers in Groups 2 + 4. The findings indicate the marked neurotropic action of MMS and EMS following postnatal and transplacental exposure. (39 refs)

79-0120 Induction of Purine Analog-resistant Mutants in Adult Rat Liver Epithelial Lines by Metabolic Activation-dependent and -Independent Carcinogens. (Eng) Tong, C. (Naylor Dana Inst. Disease Prevention, American Health Foundation, 1 Dana Road, Valhalla, NY, 10595); Williams, G. M. *Mutat Res* 58(2/3): 339-352; 1978.

In adult rat liver epithelial cultures, 6-thioguanine was superior to 8-azaguanine in the selection of purine analog-resistant mutants. The incidence of purine analog-resistant mutants increased as a result of exposure to a metabolic activation-dependent carcinogen [methyl methanesulfonate (MMS)] or to activation-independent carcinogens (aflatoxin B1, dimethyl sulfoxide, N-2-fluorenylacetamide). Expression time studies revealed that an interval of about 10 days between carcinogen exposure and mutant selection was required to recover the max number of mutants. The parental cell type and its mutants were comparable in sensitivity to the toxic effects of MMS. These data on increasing mutant incidence with time following exposure and the lack of specific resistance of the mutants to toxic effects of mutagenic carcinogens indicate that increased mutant incidence was due to mutant induction rather than to selection. Thus, rat liver epithelial cell cultures provide a self-sufficient screening system for carcinogens/mutagens. (54 refs)

79-0121 Detection of Alkylating Agents by the Analysis of Amino Acid Residues in Hemoglobin and Urine. 1. The In Vivo and In Vitro Effects of Ethyl Methanesulfonate, Methyl Methanesulfonate, Hycanthone Methanesulfonate, and Naltrexone. (Eng) Truong, L. (Preventive Medicine and Community Health, Div. Environmental Toxicology and Epidemiology, Univ. Texas Medical Branch, Galveston, TX, 77550); Ward, J. B.; Legator, M. S. *Mutat Res* 54(3): 271-281; 1978.

The effect of three alkylating agents, ethyl methanesulfonate (EMS), methyl methanesulfonate (MMS), and hycanthone methanesulfonate (HMS), and the narcotic antagonist naltrexone on the amino acid compositions of rat and human Hb was examined. Because the amino acid compositions of these proteins are well-established, changes in the molar ratios of specific amino acids could be monitored in purified Hb samples. Ratios of histidine, which is readily attacked by alkylating agents, to proline, which is not, were consistent in Hb purified from untreated blood samples from 14 male albino Sprague-Dawley rats and 25 human subjects. Treatment of Hb in vitro or in vivo with MMS, EMS, or HMS resulted in a loss of histidine residues relative to proline or phenylalanine. The decrease in histidine content increased with treatment dose and time and reached a max at about 15% of total histidine. Treatment of rats with MMS resulted in an increased urinary excretion of methylhistidines. Naltrexone had no direct effect on Hb in vitro, but it increased the proportion of methylhistidines in the urine of treated animals. (14 refs)

79-0122 Effect of 1,2-Dibromoethane (DBE) on Meiotic Chromosomes of *Tradescantia*. (Eng) Ma, T. H. (Dept. Biology, Brookhaven Natl. Lab., Upton, NY, 11973); Sparrow, A. H.; Schairer, L. A.; Nauman, A. F. *Mutat Res* 58(2/3): 251-258; 1978.

The production of micronuclei (MCN) in tetrads of microsporogenesis of *Tradescantia* clone 4430 (*T. hirsutiflora* x *T. subcaulis*) by a 6-hr treatment with 1,2-dibromoethane (DBE) gas showed a positive correlation with the concentration of DBE administered. A range of 0.001-0.002 MCN/tetrad/ppm hr was established by dose-effect experiments. The dose-response curve of the present study resembled that of a previous study on pink mutation in stamen hairs of the same clone of plants. A comparison of MCN/tetrad and pink mutation/stamen hair showed that the mutagenic efficiency of DBE in MCN induction is approx 36 times that of its efficiency in pink mutation induction. This is due to the fact that each of the 12 chromosomes of the meiocyte has many sites for chromosome or chromatid aberrations resulting in MCN, whereas only 1 site in 12 chromosomes of each stamen hair cell will permit expression of a pink mutation. (18 refs)

79-0123 Epoxide-Nucleophile Interactions: Acid-catalyzed Reaction of Ethylene Oxide with Water.

(Eng) Politzer, P. (Dept. Chemistry, Univ. New Orleans, New Orleans, LA, 70122); Daiker, K. C.; Estes, V. M.; Baughman, M. *Int J Quant Chem Quant Biol Symp* (5): 291-299; 1978.

The acid-catalyzed ring-opening interaction of ethylene oxide with water was studied. The effect of protonation in facilitating the opening of the epoxide ring involved at least two factors: a lengthening, and presumably weakening, of the C-O bonds and a change in the calculated atomic charges on the carbons from negative to positive, which should make them more reactive toward nucleophiles. A cis mode of attack by the water molecule was energetically favored over a trans mode. Several structures indicated that the key role may be played by internal hydrogen bonding. (20 refs)

79-0124 Structural Correlations of Carcinogenic and Mutagenic Alkyl Halides. (Eng) Simmon, V. F. (SRI International, Menlo Park, CA, 94025). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 163-171; 1978.

The Ames *Salmonella typhimurium* microsome assay, using strain TA100, was used to determine the mutagenicity of 23 alkyl halides, 10 of which were unknown carcinogens. Twenty-one of these halides were mutagenic with and without S-9 liver microsome mix. The mutagenic compounds (c denotes proven carcinogen) included methyl bromide, methyl chloride, methyl iodide (c), methylene chloride (c), bromochloromethane, methylene bromide, bromoform (c), dibromochloromethane, bromodichloromethane, vinyl chloride (c), vinylidene chloride (c), 1,1,2-trichloroethylene (c), bis(2-chloroethyl) ether (c), bis(2-chloroisopropyl) ether, 1-chloropropene, 3-chloropropene, epichlorohydrin (c), hexachlorobutadiene, 3-bromopropionic acid, 3-iodopropionic acid, and 3-chloropropionic acid. Two known carcinogens, carbon tetrachloride and chloroform, were not mutagenic in the presence or absence of the S-9 mix. It is likely that an insufficient amount of the mutagenic form was produced or that this form was so unstable it was unavailable to interact with the bacterial DNA. In general, the mutagenicity correlated with chemical reactivity. Of interest was the mutagenicity of methylene chloride, a widely used industrial chemical with broad environmental exposure (via paint removers and aerosol spray cans). (17 refs)

79-0125 Studies on the Mutagenicity of Vinyl Chloride Metabolites and Related Chemicals. (Eng) Laumbach, A. D. (Dept. Microbiology and Immunology, Univ. Louisville Sch. Medicine, Louisville, KY, 40201); Lee, S.; Wong, J.; Streips, U. N. In: *Third International Symposium on the Detection and Prevention of Cancer held by the*

International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 155-170; 1977.

The mutagenicity and potential mechanisms of action of several vinyl chloride (VC) metabolites [chloroacetaldehyde (CAA) monomer hydrate, CAA dimer hydrate, and CAA trimer] and epichlorohydrin (ECH, a carcinogenic chlorooxirane homolog) were studied. Indirect mutagenicity assays using repair-deficient *Bacillus subtilis* strains and direct mutagenicity assays using *Salmonella typhimurium* were performed. The mutagenicity of CAA and chlorooxirane was confirmed and that of the VC metabolites and ECH was found. Neither acetaldehyde, chloroacetic acid, nor chloroethanol showed a significant level of mutagenicity. There may be a molecular relationship involving the proximity of the chloride group to the aldehyde moiety for mutagenicity. Recombination repair appeared to be the mechanism for correcting VC metabolite-elicited damage. CAA decreased the biological activity of transforming DNA only if the cells were treated with the mutagen prior to DNA extraction. In vitro studies showed no such effect. The mode of action of ECH differed from that of the VC monomer metabolites. Although it caused similar base-substitution mutations in *Salmonella* strain TA100, it was a comparatively weaker alkylating agent. ECH also exhibited a lower toxicity level than VC monomer metabolites and thus demonstrated mutagenicity through a wider range of concentrations. ECH produced higher levels of mutation in *Salmonella* cultures that were actively replicating DNA than in cultures that were arrested in DNA replication. (29 refs)

79-0126 Mutagenicity of Aliphatic Epoxides. (Eng) Wade, D. R. (Coll. Pharmacy, Univ. Michigan, Ann Arbor, MI, 48109); Airy, S. C.; Sinsheimer, J. E. *Mutat Res* 58(2/3): 217-223; 1978.

The mutagenicity of 17 aliphatic epoxides was determined using the *Salmonella typhimurium* mutants developed by Ames. In strains TA100 and TA1535, the activity of these epoxides and those reported in the literature, depended on the degree of substitution around the oxirane ring. Monosubstituted oxiranes were the most potent mutagens in both strains. 1,1-Disubstitution resulted in the complete loss or reduction of mutagenicity. *trans*-1,2-Disubstituted and tetrasubstituted oxiranes were not mutagenic, and the *cis*-1,2-disubstituted oxiranes tested were weakly mutagenic in strain TA100 only. For the monosubstituted compounds, the presence of electron-withdrawing substituents increased mutagenicity. (17 refs)

79-0127 The Effect of Chronic Ethanol Intake on the Growth and Spread of Some Murine Tumors. (Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Jen-

ner, M.; Pinnock, M. H.; Dorrell, H. M.; Williams, D. C. *Oncology* 35(5): 224-226; 1978.

The effect of ethanol on the growth and spread of B16 melanoma, Ehrlich ascites cells, and Lewis lung carcinoma was investigated in C57BL/6 and Theiller-Original mice. The mice were divided into three groups for ethanol treatment: (1) pretreated, given a 10% ethanol soln in place of drinking water for 2 wk prior to inoculation of tumor cells; (2) post-treated, given the ethanol soln after injection of tumor cells; and (3) control, injected with tumor cells but given no ethanol. Animals from each group were inoculated im with 4.6×10^6 B16 melanoma cells, ip with 3.5×10^6 Ehrlich ascites cells, or im with 2×10^6 Lewis lung carcinoma cells. There was no significant difference between the pre- and posttreated animals. The treatment had no effect on the B16 melanoma, but the number of Ehrlich ascites cells were reduced by ethanol ingestion. In the case of the Lewis lung carcinoma, administration of ethanol for 2 wk tended to lower the number of metastases to the lung without significantly affecting the primary tumor size; more prolonged ethanol intake (up to 8 wk) decreased both the wt of the primary tumor and the rate of metastasis to the lung. The inhibitory effect of ethanol on metastasis and primary tumor growth could be due to an effect on the metabolism of the host and/or the tumor. The replication of the tumor cells may have been limited by an ethanol-induced decrease in nutrients or energy availability. These results do not corroborate reported correlations between alcohol intake and increased tumor incidence in humans. (18 refs)

79-0128 The Effect of Chloroform Ingestion on the Growth of Some Murine Tumours. (Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Williams, D. C. *IRCS Med Sci (Cancer)* 6(10): 435; 1978.

Administration of chloroform (in drinking water) to male T0 mice did not enhance the growth or metastasis of Lewis lung carcinoma (LLC) or significantly increase the number of Ehrlich ascites tumor (EAT) cells at a level of 0.15 mg/kg/day. At 15 mg/kg/day, there was a significant increase in LLC foci and in the number of EAT cells. The percentage of organs invaded by B16 melanoma cells was greater in animals treated with either dose level than in controls. (4 refs)

79-0129 Immunopathologic Observations in Liver Angiosarcoma. (Eng) Espinosa, E. (Dept. Pathology, Univ. Louisville Sch. Medicine, Louisville, KY). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 927-939; 1977.*

To develop a more sensitive liver function test for the early detection of vinyl chloride liver disease, an attempt was made to discover antigenic changes in angiosarcomatous tissue and to test for the presence of an antibody response in the host. Serum, liver, and adjacent tissue samples were obtained at autopsy from 2 individuals with vinyl chloride-associated angiosarcoma and 10 control individuals with normal liver function and at biopsy from 10 patients with liver dysfunction with fibrosis. Immunodiffusion studies of angiosarcomatous tissue revealed the presence of an antigen not found in normal liver or kidney, but found in normal lung and spleen. This protein was inactivated by Pronase and trypsin, was heat- and acid pH-labile, and was found to precipitate at concentrations of 20-30% saturated ammonium sulfate and 30-70% ethanol. Immunoelectrophoretic assays of angiosarcomatous tumor extracts revealed the absence of one normal tissue antigen characterized as an entity unaffected by Pronase, trypsin, and heat treatment, inactivated by periodate and acid pH, and which precipitated over a wide range of conditions. Additionally, immunofluorescence assays of angiosarcomatous tissue indicated the presence of bound IgG. Further studies are necessary to determine whether this tumor-bound IgG represents specific antitumor antibody or antibody fixed by the tumor tissue nonspecifically. (29 refs)

79-0130 Urinary and Tissue Glycosaminoglycan Patterns in Hepatic Angiosarcoma. (Eng) Kupchella, C. E. (Cancer Center, Dept. Medicine, Univ. Louisville Sch. Medicine, Louisville, KY, 40201); Tamburro, C. H. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 915-926; 1977.

To evaluate the use of glycosaminoglycan (GAG) patterns as an early indicator of vinyl chloride (VC)-induced liver injury or angiosarcoma (AS), GAG patterns were determined in urine samples of 9 patients with histories of exposure to VC and who had abnormal liver biochemistry, 6 with "other" cancers prior to surgery, 3 with AS, 8 with viral hepatitis, 6 with cirrhosis, 2 with lung-liver metastases, and 4 with metabolic liver disorders. Determinations of GAG were carried out by creatinine and uronic acid assays. Additionally, tissue samples taken at autopsy from 2 patients with AS, 2 with cirrhosis, and 3 controls (who had gun-shot wounds) were similarly analyzed. Results showed that AS, hepatitis, cirrhosis, and liver metastases all involved elevated GAG excretion. Tissue data indicate that these elevated levels reflect GAG elevation in the liver. Furthermore, results disclosed that the chondroitin sulfates are the primary urinary GAG in both normal controls and in patients, while chondroitin sulfates and heparin are the dominant GAG present in fibrotic, nontumor portions of AS livers and tumor tissue, respectively. It is concluded that the increases in liver and urinary GAG levels may well reflect an important role of

these substances in the process of fibrogenesis and tumor growth. (31 refs)

79-0131 Electronic Properties of Protein--Methylglyoxal Complexes: Strong Evidence for Energy-Band Conduction. (Eng) Pethig, R. (Lab. Natl. Foundation Cancer Res., Univ. Coll. North Wales, Dean St., Bangor, Gwynedd LL57 1UT, Wales). *Int J Quant Chem Quant Biol Symp* (5): 159-171; 1978.

Further studies were made of the dielectric and electronic properties of various protein-methylglyoxal (MG) complexes. Piezoelectric properties, microwave Hall effect, hydration isotherm properties, steady-state conduction, and dielectric properties were measured over the effective frequency range 10^{-5} to 10^{10} hertz. The extent of the binding of MG was established using ^{14}C -labeled MG and scintillation counting. The interaction of MG with proteins resulted in a brown complex that exhibited increased electronic activity compared with normal untreated proteins. This complex had an increased free-electron spin density, steady-state conductivity, and piezoelectric response. Unlike the untreated proteins, the protein complexes also exhibited a distinct low-frequency dielectric dispersion, and at 10 gigahertz there was a reversal of the usual electric-field saturation of polarizability. Compared with normal casein, the casein complex exhibited an increase in monolayer hydration capacity. These effects suggest that when MG is incorporated into the structure of a protein molecule, a charge-transfer interaction occurs, resulting in the creation of mobile electron "holes." This satisfies the basic prerequisite for the applicability of Szent-Gyorgyi's electronic theory of the "living state" and of cancer. (30 refs)

79-0132 Plasmacytomas of the NZB Mouse. (Eng) Morse, H. C. (Lab. Microbial Immunity, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD, 20014); Riblet, R.; Asofsky, R.; Weigert, M. *J Immunol* 121(5): 1969-1972; 1978.

Myeloma proteins derived from distinct genetic pools were compared for sequence specificity differences or similarities following plasmacytoma induction in > 10,000 NZB mice (6-8 wk of age) that were injected ip with 0.05 ml pristane (2,6,10,14-tetramethylpentadecane) at three bimonthly intervals. Approx 50% of the total number of tumors were induced by 1 yr, and the rest developed before 20 mo, but this induction period was longer than that previously observed for BALB/c mice. Of these tumors, 77% were diagnosed as plasmacytomas. Samples of tumor ascites fluids were analyzed for paraproteins by immunoelectrophoresis with specific antisera and the results compared with a previously reported series of BALB/c mice plasmacytomas; 82% of NZB ascites contained a detectable paraprotein (similar to the BALB/c series), but fewer NZB ascites contained IgA (20.3% versus

45.5%) and more contained IgG (41.7% versus 19.7%) than in the BALB/c series. Furthermore, 8.2% of NZB ascites contained paraproteins that could not be assigned to a particular heavy chain class, whereas all ascites were classifiable in the BALB/c series. Only 4/595 paraprotein-containing NZB ascites bound any carbohydrate antigen tested, 10x less than in the BALB/c series. Although 56 NZB tumors produced ascites with more than one paraprotein, 0/25 were shown to produce more than one following serial transplantation, indicating that these polysecreting tumors probably reflected the independent occurrence of two separate malignant clones. The observed differences between the two series suggest that the cell populations susceptible to malignant transformation may be different in BALB/c and NZB mice. (13 refs)

79-0133 Combined Cytogenetic Effects of Endosulfan & Metepa in Male Rats. (Eng) Dikshith, T. S. (Industrial Toxicology Res. Centre, Lucknow 266 001, India); Nath, G.; Datta, K. K. *Indian J Exp Biol* 16(9): 1000-1002; 1978.

The combined effects of endosulfan (ES, a widely used insecticide and acaricide) and metepa (MT, a sterilizing agent against insect vectors) on the chromosomes of male albino rats were studied. The rats were given ES (11.6 mg/kg/day) and/or MT (13.6 mg/kg/day) po for 30 days. Cytogenetic assays of bone marrow and spermatogonial cells showed that ES did not cause any significant chromosomal aberrations in the rats. However, MT alone and in combination with ES increased the number of aberrant cells and chromatid breaks in spermatogonial and bone marrow cells, particularly in the latter. These increases were greater with MT alone. The mitotic index in control, ES-, ES- + MT-, and MT-treated cells was 56%, 26.6%, 19.13%, and 22.29%, respectively, in the bone marrow cells and 28%, 21%, 11.08%, and 14.16% in the spermatogonial cells. The results show that MT produces significant cytogenetic changes in the rat and that ES and MT do not potentiate each other. (19 refs)

79-0134 Cytotoxic Effects of Toximul MP8 in Human Lymphocytes in Culture: A Preliminary Investigation. (Eng) Petropolis, P. N. (Lab. Radiation Biology, Dalhousie Univ., Halifax, Nova Scotia, Canada); Kamra, O. P. *Mutat Res* 58(2/3): 287-291; 1978.

The cytotoxic effects of Toximul MP8 a commercial emulsifier formulation used as an insecticide carrier, on human lymphocytes were assessed by measuring mitotic index, DNA labeling index, and the frequency of chromatid breaks. The Toximul MP8 was added in amounts of 10, 20, 30, or 40 ppm together with phytohemagglutinin to human whole blood, which was cultured for 52 hr. The mitotic index decreased from 10.44% at 0 ppm to 0.24% at 40 ppm. The percent of lymphocytes incorporating (³H)thymidine from 32-35 hr of

culture also decreased with an increase in the Toximul MP8 concentration. The labeling index of 17.38% in control cultures dropped to 5.62% and 0.39% at 20 and 40 ppm, respectively. A significantly increased percentage of abnormal metaphases was observed even at the 10 ppm Toximul MP8 concentration. Based on these preliminary studies, the continued use of Toximul MP8 as an insecticide carrier-emulsifier in an aerial spray program in populated areas should be questioned. (12 refs)

79-0135 Mutagenic Action of Aromatic Epoxy Resins. (Eng) Andersen, M. (Dept. Microbiology, Royal Danish Sch. Pharmacy, 2 Universitetsparken, DK-2100 Copenhagen O, Denmark); Kiel, P.; Larsen, H.; Maxild, J. *Nature* 276(5686): 391-392; 1978.

Three aromatic epoxy resins, Epikote 828 (E828), Epikote 1001 (E1001), and Epikote 1004 (E1004) were tested for mutagenicity by comparison with the positive control substance epichlorhydrin (ECH; a simple epoxide) in the plate incorporation assay with histidine-requiring mutants of *Salmonella typhimurium*. E828, the most active resin tested, and E1001 were both more mutagenic than was ECH in tester strain TA100. Although the mutagenicity of ECH was similar in both tester strains TA100 and TA1535, that of the resins was much lower in TA1535 than in TA100, showing that residual ECH in the resins was not the sole cause of the resins' actions. When rat liver microsomes containing NADP were added to the culture plates, the activities of both the resins and of ECH decreased 10-fold in strain TA100; whereas in strain TA1535, E828 was activated in the presence of NADP, and inactivated in its absence. E1001 showed a similar tendency in relation to NADP. The activity of ECH was reduced almost 10-fold in TA1535 assay with microsomes, independent of the presence of NADP. The activation of the epoxy resins seen in TA1535 was not caused by decomposition of the compounds and liberation of constituent bisphenol A (2,2-bis(4-hydroxyphenyl)propane), because this compound was not mutagenic in either tester strain with or without added liver microsomes when tested separately. The results demonstrate a potential cancer risk in man from the three resins tested. (16 refs)

79-0136 Mutagenic Action of Some Hair Dyes Manufactured in Czechoslovakia. (Cze) Havova, R. (Lekarska Fakulta, UJEP, Brno, Czechoslovakia); Soskova, L.; Hava, P. *Cesk Hyg* 23(9): 383-388; 1978.

Twenty-five Czechoslovakian Regonol hair dye preparations were tested for antigenicity in the Ames test, using *Salmonella typhimurium* strains TA 98, TA 100, TA 1535, TA 1537, and TA 1538. The Regonol preparations contain p-phenylenediamine, resorcinol, p-aminophenol, p-nitro-o-aminophenol, o-nitro-p-phenylenediamine and picramic acid. Seven preparations showed marked mutagenic

activity. Twenty preparations were tested with TA 98 with activation by mouse liver microsomal fraction. Thirteen preparations were found to be mutagenic, and two others suspect as mutagenic in this test. All mutagenically active preparations reacted with the detector strains TA 98 and TA 1538, which detect mutations in guanidine and cytosine sequences. The findings suggest that these dyes are potentially dangerous for their users, and especially for hairdressers and persons engaged in their manufacture. (22 refs)

- 79-0137 Half-wave Potentials and LCAO-SCF-MO Calculations for Carcinogenic Benz(c)acridines.** (Eng) Okano, T. (Pharmaceutical Inst., Tohoku Univ., Tohoku, Japan); Haga, M.; Ujii, K.; Motohashi, N. *Chem Pharm Bull (Tokyo)* 26(9): 2855-2859; 1978.

The half-wave reduction potential and half-peak oxidation potential were measured for 11 methyl-substituted benz(c)acridines and unsubstituted benz(c)acridine in acetonitrile with tetraethylammonium perchlorate electrolyte. A linear correlation was obtained between the energy of the lowest unoccupied molecular orbital as calculated by the LCAO-SCF method and the half-wave reduction potential. A correlation also existed between the energy of the highest occupied molecular orbital and the half-peak oxidation potential. The carcinogenic activities of the derivatives were highly correlated with the electron density, the electrophilic superdelocalizability of the K-region, the electron density for the ring nitrogen atom of the compound, and the reactivity index. The data suggest that the electrophilic reactivity of the K-region or the ring nitrogen atom is almost essential for the carcinogenic activity of the methyl-substituted benz(c)acridines. (16 refs)

- 79-0138 Carcinogenic Benzo(a)pyrene Metabolites Bound to DNA: Metabolic Formation by Human Cultured Lymphocytes and by Human Liver Microsomes.** (Eng) Boobis, A. R. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014); Atlas, S. A.; Nebert, D. W. *Pharmacology* 17(5): 241-248; 1978.

The formation of carcinogenic benzo(a)pyrene (BP) metabolites that bind to DNA by cultured human lymphocytes and human liver microsomes was investigated. Cultured human lymphocytes were activated by incubation with pokeweed mitogen plus phytohemagglutinin M prior to treatment with 3-methylcholanthrene (MC). Sonicates of these cells were incubated with deproteinized DNA (20 mg), (³H)BP (60 nmol), and an NADPH-generating system. With both control and MC-treated lymphocytes, two BP metabolite-nucleoside chromatographic peaks were detected. The major peak represented the 4,5-oxide bound to nucleoside(s) and the lesser

represented quinone-oxide(s). There was no correlation between the aryl hydrocarbon hydroxylase activity (or its inducibility) and the BP metabolites generated by the lymphocytes and bound to DNA in vitro, due perhaps to limiting amounts of epoxide hydase in cultured human lymphocytes; it is further suggested that, in tissues such as lung, which have very low epoxide hydase activity, intermediates such as those generated by further metabolism of quinones or the 4,5-oxide may represent the ultimate carcinogenic forms. At least six BP metabolite-nucleoside chromatographic peaks were identified when human liver microsomes were examined. The major peak represented the 7,8-diol-9,10-epoxides bound to nucleoside, which is believed to be one of the ultimate carcinogenic forms of BP. It is suggested that it might be possible, by assaying liver or other tissue from a number of subjects, to determine if there are inter-individual differences in the capacity to produce this metabolite. (42 refs)

- 79-0139 Potentiation of Steroid Binding to Proteins by 7,12-Dimethylbenz(a)anthracene.** (Eng) Barlow, J. W. (Downie Metabolic Unit, Alfred Hosp., Prahran, Victoria, Australia, 2010); Minasian, L. C.; Funder, J. W. *J Steroid Biochem* 9(11): 1027-1032; 1978.

The possibility that the carcinogenic action of 7,12-dimethylbenz(a)anthracene (DMBA) may occur through an interaction with target tissue receptors for steroid hormones was studied. Cytosols were prepared from uterus and mammary gland of 45-day-old adrenalectomized and ovariectomized rats that had been either untreated or primed with estradiol benzoate (0.4 mg/100 g/day sc for 3 days prior to sacrifice). The cytosols were incubated for 90 min with various steroids with and without DMBA (10^{-6} M). DMBA did not affect the binding of (³H)-estradiol or of (³H)-dexamethasone but increased the binding of (³H)-progesterone [(³H)-P; 10^{-8} M]. The enhanced binding of (³H)-P in the presence of DMBA was specific, since it was displaceable by excess unlabeled P. Potentiation of (³H)-P binding was not confined to potential P target tissues; DMBA also potentiated binding of ³H-P to bovine serum albumin, ovalbumin, catalase, and rat plasma. Over the range of protein and DMBA concentrations studied, potentiation of (³H)-P binding increased with increasing DMBA concentrations (1-30 μ M) and decreased with increasing protein concentrations (0.003-0.1 mg/ml). Potentiation appeared restricted to a protein concentration < 1 mg/ml. Among a number of steroids studied, the hierarchy of DMBA-potentiated binding was (³H)-P > (³H)-R 5020 (17,21-dimethyl-19-nor-4,9-pregnadiene-3,20-dione) > (³H)-deoxycorticosterone. 3-Methylcholanthrene, a less potent carcinogen than DMBA, had a similar but much less marked potentiating effect on steroid binding. A 10-fold increase in DMBA concentration resulted in a 100-fold increase in bound (³H)-P, indicating a cooperative phenomenon. These results suggest that DMBA may be active at a precellular level via modification of the effector actions of progesterone. (15 refs)

79-0140 Cytogenetic Toxicity of Gentian Violet and Crystal Violet on Mammalian Cells In Vitro.

(Eng) Au, W. (Dept. Biology, Univ. Texas System Cancer Center, M. D. Anderson Hosp., Tumor Inst., Houston, TX, 77030); Pathak, S.; Collie, C. J.; Hsu, T. C. *Mutat Res* 58(2/3): 269-276; 1978.

The cytogenetic toxicity of gentian violet (a triphenylmethane dye) and its related compound, crystal violet, were tested in various mammalian cells in vitro. Chinese hamster ovary (CHO) cells treated for 8 hr with a 10 µg/ml gentian violet showed a significant accumulation of abnormal metaphases as evidenced by their elevated mitotic index and metaphase/anaphase ratio. The chromosome aberrations induced by gentian violet were both dose- and duration-dependent. At 0.5 and 5.0 µg/ml, gentian violet also induced chromosome aberrations in human lymphocyte cultures, HeLa cells, L cells, and in fibroblast lines derived from *Peromyscus eremicus* and from the Indian muntjac. At 5 µg/ml gentian violet, the *Peromyscus* cells exhibited complete mitotic inhibition. In a comparative study of the effect of 11 triphenylmethane dyes (various gentian and crystal violets) on the chromosomes of CHO cells, most dye samples induced severe damage to chromosomes. These results indicate that both gentian violet and crystal violet are clastogenic and should be regarded as biohazardous substances. (16 refs)

79-0141 Clinical and Pathological Effects of Cigarette Smoke Exposure in Beagle Dogs. (Eng) Zwick-

er, G. M. (Stauffer Chemical Co., Farmington, CT); Filipy, R. E.; Park, J. F.; Loscutoff, S. M.; Ragan, H. A.; Stevens, D. L. *Arch Pathol Lab Med* 102(12): 623-628; 1978.

The clinical and pathological effects of high (4.6 mg) nicotine (HN) and low (1.4 mg) nicotine (LN) cigarette smoke administered via tracheostomy to young adult male beagle dogs in doses of 6 or 12 cigarettes/day were determined. The dogs were exposed 7 days/wk for 5 mo. Tracheobronchitis was common in dogs given 12 HN cigarettes/day, with accompanying recurrent fever and thick discharge from the tracheal stroma. In dogs given 12 cigarettes/day, leukocytosis was consistently noted in both HN- and LN-treated animals throughout the exposure period. At necropsy, the left diaphragmatic lobe of the lungs was significantly heavier in dogs exposed to 12 cigarettes/day; the right apical lobe was significantly heavier in all the smoke-exposed dogs. Lesions were confined primarily to the lungs and tracheobronchial lymph nodes, which were approx 2X normal size and discolored brownish-black. Histopathologically, there were basal cell hyperplasia of the larynx, trachea, bronchial tree, and respiratory mucosa; alveolitis and alveolar type 2 epithelial cell hyperplasia; alveolar histiocytosis; "smoke granulomas"; and fibrosis in virtually all smoke-exposed animals. Dogs on 12 cigarettes/day-regimens usually also had accompanying squamous metaplasias, and in these animals there were three cases of suppurative bronchopneumonia (all were HN trea-

ted). Rhinitis, turbinate basal epithelial cell hyperplasia, and squamous metaplasia were increased in dogs in the HN versus those in the LN cigarette group. Alveolar emphysema was infrequently found, but it is suggested that this was due to the relatively short duration of the experiment. (25 refs)

79-0142 Formation and Determination of Ethyl Carbamate in Tobacco and Tobacco Smoke. (Eng)

Schmeltz, I. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Chiong, K. G.; Hoffmann, D. *J Anal Toxicol* 2(6): 265-268; 1978.

The formation of ethyl carbamate (EC, urethan) from maleic hydrazide (MH) was investigated in model studies, and a method for determining EC in tobacco products was developed. The method includes solvent partition, column chromatography, and gas chromatography/mass spectrometry. The smoke of MH-treated and untreated tobaccos contained comparable amounts of EC (20-38 nanograms/cigarette), as did treated and untreated tobaccos (310 and 375 nanograms/g, respectively). (13 refs)

79-0143 Exposure of Nonsmokers to the Gaseous and Particulate Phases of Cigarette Smoke. (Dan)

Hugod, C. (Klinisk-kemisk afdeling CL, Rigshospitalet, DK-2100 Copenhagen O, Denmark); Hawkins, L.; Astrup, P. *Ugeskr Laeg* 140(44): 2707-2711; 1978.

The effects of exposing volunteers to different components of sidestream cigarette smoke in an unventilated room were determined. The concentrations of both the gaseous and particulate components of the cigarette smoke decreased, probably due to inhalation and adsorption on the skin, hair, and clothing of the volunteers. However, it is emphasized that when healthy nonsmokers are exposed to tobacco smoke under realistic circumstances, they are not exposed to levels that would produce a permanent health hazard. (25 refs)

79-0144 Characterization of Catechols, Resorcinols, and Hydroquinones in an Acidic Fraction of Cigarette Smoke Condensate. (Eng) Schlotzhauer, W. S. (Natl.

Inst. Environmental Health Service, Research Triangle Park, NC, 27709); Walters, D. B.; Snook, M. E.; Higman, H. C. *J Agric Food Chem* 26(6): 1277-1281; 1978.

Gel filtration chromatography, gas chromatography-mass spectrometry, and UV spectroscopy showed that a biologically active subfraction of a weakly acidic fraction of cigarette smoke condensate contained catechol, resorcinol, and hydroquinone and their alkyl and methoxy derivatives plus 4-pyrone, vanillins, dimethoxyphenols, phenylphenols, and naphthols. (19 refs)

- 79-0145** High Pressure Liquid Chromatographic Determination of Patulin in Apple Juice. (Eng) Stray, H. (Food Inspection of Processed Fruits and Vegetables, Ministry Agriculture, Gladengyn, 3B, Oslo 6, Norway). *J Assoc Off Anal Chem* 61(6): 1359-1362; 1978.

The patulin (PL) content of 140 apple juice samples was analyzed. PL was extracted from apple juice with ethyl acetate, the extract was purified by elution from a silica gel column with ethyl acetate-toluene, and the eluate was subjected to high-pressure liquid chromatography. The samples contained $< 1\text{-}220\text{ }\mu\text{g/liter}$ PL. The lower detection limit was $1\text{ }\mu\text{g/liter}$; the mean recovery of added PL was 82.6%. (5 refs)

- 79-0146** Differential Expression of Oncogenicity and Nopaline Synthesis in Intact Leaves Derived from Crown Gall Teratomas of Tobacco. (Eng) Wood, H. N. (Lab. Plant Biology, Rockefeller Univ., New York, NY, 10021); Binns, A. N.; Braun, A. C. *Differentiation* 11(3): 175-180; 1978.

The expression of oncogenicity and nopaline synthesis in crown gall teratoma tissues of tobacco was studied. The expansion phase of teratoma-derived leaf tissue fragments planted on a basic culture medium could be reproduced in normal leaf tissues when fragments of the latter were isolated and planted on basic culture medium supplemented with an auxin (naphthaleneacetic acid, 0.25 mg/liter). Thus, auxin was persistently synthesized in the isolated teratoma-derived fragments. An active, de novo synthesis of nopaline from arginine occurred in the essentially resting cells present in intact teratoma-derived leaves, but it did not appear to occur in intact normal tobacco leaves of comparable age and stage of development. The data indicate that while an active and persistent de novo synthesis of nopaline occurs in intact teratoma-derived leaves, a reexpression of oncogenicity depends on the development of new cell divisions. These new cell divisions may be required to reestablish positive feedback control mechanisms upon which the development of a capacity for autonomous tumor tissue growth depends or to establish the pattern of metabolism concerned with cell growth and division that is then maintained in the plant tumor cells by positive feedback control mechanisms. (8 refs)

- 79-0147** Effect of Agrocin 84 on Attachment of *Agrobacterium tumefaciens* to Cultured Tobacco Cells. (Eng) Smith, V. A. (Dept. Biochemistry, Univ. Bristol Medical Sch., University Walk, Bristol, England); Hindley, J. *Nature* 276(5687): 498-500; 1978.

Initial stages in the transformation of cultured tobacco cells to crown gall tumor cells by *Agrobacterium tumefaciens* C58 were investigated, along with the role of agrocin 84 (A84), an intraspecific antibiotic produced by the nonpathogenic

strain *A. tumefaciens* K84, in preventing tumorigenesis. Tobacco cell cultures and wounded tobacco plants were inoculated with aliquots of untreated and A84-treated suspensions of strain C58 (which harbors the nopaline-type tumorigenic plasmids) and its avirulent, heat-cured derivative C58(NT-1). The cultures of C58 that induced tumor formation on wounded plants also induced nopaline synthesis in the cells, and both processes were blocked by A84. C58(NT-1) did not induce transformation. When C58 and C58(NT-1) were labeled with ^{32}P before A84 treatment and the experiments were repeated, it was found that $> 90\%$ of C58 remained associated with the tobacco cells after fractionation, vs only 15% of C58(NT-1). A84 reduced the affinity of C58 for its host by a factor of 2-3, but it did not significantly alter the binding capacity of C58(NT-1). Scanning electron microscopy of the infected tobacco cells demonstrated that the formation of a specific infection complex is essential for tumorigenesis. The envelopes of the A84-treated C58 cells, but not those of treated C58(NT-1) cells, were, when present, ill-defined and fragmented, and the cells contained large, electron-dense granules. Thus, A84 probably interferes with cell wall synthesis rather than acting on preformed structures; the granules may represent a build-up of cell wall precursors. The data suggest that the cell surfaces of C58 and C58(NT-1) are different and that this difference is due to the presence of the tumorigenic plasmid. A84 may prevent tumorigenesis by causing fragmentation or loss of the cell envelope, thereby impairing the ability of the bacterium to transfer tumorigenic DNA to its host. (28 refs)

- 79-0148** The Lack of Mutagenic Properties of Patulin and Patulin Adducts Formed with Cysteine in *Salmonella* Test Systems. (Eng) von Wright, A. (Technical Res. Center of Finland, Food Res. Lab., Biologinkuja 1, SF-02150, Espoo 15, Finland); Lindroth, S. *Mutat Res* 58(2/3): 211-215; 1978.

The fungal toxin patulin and patulin-cysteine adducts were tested for mutagenicity in an Ames'-type assay with *Salmonella typhimurium* strains TA100 and TA98, both in the presence and absence of a liver microsome preparation from male NMRI mice. Patulin in the amounts of 5, 10, 20, and $30\text{ }\mu\text{g}$ and patulin adducts of 900, 1,800, and 2,700 patulin-equivalent μg were tested. No mutagenicity was noted in any of the microsomal activation tests. A host-mediated assay was performed using *S. typhimurium* strains TA1950 and TA1951 in which gastric intubation of 20 and 10 mg/kg patulin or 2,800 and $1,400\text{ mg/kg}$ adduct mixture into NMRI mice was followed by injection of bacterial strains into the mouse peritoneum, incubation for 3 hr, retrieval of incubated peritoneal fluid, and plating of the bacteria. No differences were found in injected animals either internally or externally, and there were no differences in revertant frequencies or in viable counts of test bacteria. These results suggest that patulin reacts with some cell component to produce a secondary effect on the genetic apparatus of the cell that is not detectable in the *Salmonella* test system. (19 refs)

- 79-0149 Mutagenicity of Plant Flavonoids: Structural Requirements for Mutagenic Activity in *Salmonella typhimurium*.** (Eng) Macgregor, J. T. (Western Regional Res. Center, U.S. Dept. Agriculture, Berkeley, CA, 94710); Jurd, L. *Mutat Res* 54(3): 297-309; 1978.

Forty compounds that are structurally related to the plant flavonol quercetin were tested for mutagenic activity in *Salmonella typhimurium* strain TA98. Quercetin, myricetin, rhamnetin, galangin, kaempferol, tamarixetin, morin, 3'-O-methylquercetin, 7,4'-di-O-methylquercetin, and 5,7-di-O-methylquercetin exhibited unequivocal mutagenic activity. Quercetin, myricetin, rhamnetin, and 5,7-di-O-methylquercetin were active without metabolic activation, although it markedly enhanced their activity, whereas the other compounds required an in vitro rat-liver metabolizing system for significant activity. Quercetin and 2,3-dihydroquercetin exhibited weak mutagenic activity. Structural features that appear essential for mutagenic activity in TA98 are a basic flavanoid ring structure with these additional features: (1) a free hydroxyl group at the 3 position, (2) a double bond at the 2,3 position, (3) a keto group at the 4 position, and (4) a structure that permits the proton of the 3-hydroxyl group to tautomerize to a 3-keto compound. A B-ring structure that permits oxidation to quinoid intermediates appears to be a requirement. The same structural requirements appear to be necessary for mutagenicity in strain TA100. A metabolic pathway for flavonol activation to DNA-reactive species is proposed. (19 refs)

- 79-0150 Comparative Mutagenesis of Plant Flavonoids in Microbial Systems.** (Eng) Hardigree, A. A. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Epler, J. L. *Mutat Res* 58(2/3): 231-239; 1978.

The plant flavonoids quercetin (3,5,7,3',4'-pentahydroxyflavone), morin (3,5,7,2',4'-pentahydroxyflavone), kaempferol (3,5,7,4'-tetrahydroxyflavone), chrysin (5,7-dihydroxyflavone), fisetin (3,7,3',4'-tetrahydroxyflavone), myricetin (3,5,7,3',4',5'-hexahydroxyflavone), myricitrin (myricetin -3- rhamnoside), hesperetin (3',5,7-trihydroxy -4'-methoxyflavanone), quercitrin (quercetin-3-L-rhamnoside), rutin (quercetin-3-rhamnosylglucoside or quercetin-3-rutinoside), and hesperidine (hesperetin-7-rutinoside) were assayed for mutagenicity in the *Salmonella*/microsomal activation system. Quercetin, morin, kaempferol, fisetin, myricetin, quercitrin, and rutin were mutagenic with *Salmonella* strain TA98. Quercetin and myricetin were mutagenic without metabolic activation, although more effective when a rat liver microsomal preparation was included; the other flavonoids all required metabolic activation. The results with *Salmonella* were confirmed in strain D4 of *Saccharomyces* and in *Escherichia coli* using various concentrations of quercetin. The results suggest that a frameshift mechanism of mutagenesis is involved. The clear possibility that these naturally occurring and ubiquitous flavonoid compounds may be mutagenic (or carcinogenic) should be investigated in higher organisms. (20 refs)

- 79-0151 Identification of a Mutagenic Substance in a Spice, Sumac, as Quercetin.** (Eng) Seino, Y. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Nagao, M.; Yahagi, T.; Sugimura, T.; Yasuda, T.; Nishimura, S. *Mutat Res* 58(2/3): 225-229; 1978.

The identification of the mutagenic substance in the spice sumac is reported. The active principle was purified and characterized by thin-layer chromatography, UV-absorption spectroscopy, and mass spectrometry. The mutagenic effects of the purified material and authentic quercetin on *Salmonella typhimurium* strains TA100 and TA98 with and without a rat liver microsomal preparation were similar under every condition tested. The UV absorption spectra of the purified sample from sumac and of authentic quercetin were also the same as was the low-resolution mass spectrum. It is concluded that all the mutagenic activity of sumac is due to quercetin. (16 refs)

- 79-0152 A Simple Solid-Phase Radioimmunoassay for Aflatoxin B₁.** (Eng) Sun, P. S. (Food Res. Inst., Univ. Wisconsin, Madison, WI, 53706); Chu, F. S. *J Food Safety* 1(1): 67-75; 1977.

A solid phase radioimmunoassay for aflatoxin B₁ is described. The method involves the incubation of labeled and unlabeled aflatoxin with IgG-sepharose gel followed by a filtration step. The binding capacity is determined by counting the radioactivity in the filtrate. The results with this method indicate that the technique can be successfully applied to the analysis of small mol wt ligands. Using a simple extraction procedure without clean-up step, the recovery yields of aflatoxin B₁ in contaminated corn or wheat at levels of ≥ 5 ppb were above 60%. (11 refs)

- 79-0153 Reverse Phase High Pressure Liquid Chromatographic Determination of Aflatoxins in Foods.** (Eng) Beebe, R. M. (Food and Drug Admin., 50 United Nations Plaza, San Francisco, CA, 94102). *J Assoc Off Anal Chem* 61(6): 1347-1352; 1978.

A method for determining aflatoxins by high-pressure liquid chromatography (HPLC) with fluorescence detection after CB extraction and cleanup was applied to various foods. Recoveries at 1- to 15-ppb levels from green coffee and peanut butter were 72%-85% and 74%-104%, respectively. The advantages of the HPLC method are speed, precision, sensitivity, selectivity, and immediate chemical confirmation of aflatoxin B₁ and G₁. (18 refs)

- 79-0154 Factors Affecting Formation of Aflatoxin B₁ by *Aspergillus flavus* on Ganga-5 Maize Hybrid**

(Letter to Editor). (Eng) Prakash, O. (Dept. Plant Pathology, Rajasthan Coll. Agriculture, Udaipur, India); Siradhana, B. S. *Curr Sci (Bangalore)* 47(18): 695-696; 1978.

Seeds of hybrid Ganga-5 maize were sterilized, inoculated with *Aspergillus flavus*, and incubated, and conditions optimal for the formation of aflatoxin B₁ (AFB₁) by the mold were determined. AFB₁ formation was max in daylight at a temperature of 25 C, incubation period of 12 days, and relative humidity of 100%. At 25 C and 100% humidity, AFB₁ could be formed within 4 days. (6 refs)

79-0155 Thin Layer Chromatographic Determination of Aflatoxin B₁ in Corn Silage. (Eng) Haggblom, P. E. (Inst. Physiological Botany, Univ. Uppsala, S-751 21 Uppsala 1, Sweden); Casper, H. H. *J Assoc Off Anal Chem* 61(6): 1363-1365; 1978.

Determination of aflatoxin B₁ (AFB₁) in moldy or nonmoldy corn silage by thin layer chromatography (TLC) is described. The toxin is extracted, purified by a combination of cleanup procedures, and analyzed by TLC. The estimated detection limit was 5 µg AFB₁/kg corn silage; 73% of the added AFB₁ was recovered. (9 refs)

79-0156 Aflatoxin Inactivation in Corn by Ammonia Gas: Laboratory Trials. (Eng) Brekke, O. L. (Northern Regional Res. Center, Agricultural Res., Science and Education Admin., U.S. Dept. Agriculture, Peoria, IL, 61604); Stringfellow, A. C.; Peplinski, A. J. *J Agric Food Chem* 26(6): 1383-1389; 1978.

The effect of several process variables on the degree of aflatoxin B₁ (AFB₁) inactivation obtained by treating a stationary bed of corn with a recycling mixture of NH₃ and air was investigated. An NH₃-air mixture was recycled at 25 C through a glass column containing AFB₁-contaminated, shelled corn until a uniform distribution of NH₃ in the corn bed was achieved. After ammoniation and sealed storage at 17.6% moisture and 25 C for 14 days' total reaction time, the AFB₁ level was reduced from 1,000 µg/kg (ppb) to 10 g/kg. The effects of varying the NH₃ level, corn moisture, reaction time, initial AFB₁ level in corn, and recycle gas flow rate were investigated. A pilot-scale experiment wherein 4.86 metric tons of 11% moisture corn was treated with 1.1% of NH₃ reduced the AFB₁ level of the corn from 90 µg/kg to a nondetectable level during 7 mo of storage indoors. Swine feeding tests on this ammoniated corn gave good results. Aqua and gaseous NH₃ appeared equally effective for inactivating the AFB₁ in corn. The data indicate that there is a degree of flexibility among various factors, such as recycle gas flow rate and recirculation time, to achieve a uniform NH₃ distribution throughout the stationary corn bed and between corn moisture and NH₃ level to achieve detoxification. 79-0157 Mycotoxin Producing Potential of Fungi Associated with Dry Shrimps. (Eng) Wu, M. T. (Dept. Nutrition and Food Science, Utah State Univ., Logan, UT, 84322); Salunkhe, D. K. *J Appl Bacteriol* 45(2): 231-238; 1978.

Among 114 fungi isolated from 20 dry shrimp samples (10 showing mold growth and 10 showing no mold growth), 27 isolates (16 *Aspergillus* cultures, 9 *Penicillium* cultures, and chloroform extracts of *Alternaria* and *Cladosporium* species) were toxic to White Leghorn chicken embryos. Ninety-nine of the isolates came from visibly moldy shrimp samples. Visibly moldy dry shrimps had a significantly higher moisture content than nonmoldy samples. *Penicillium* and *Aspergillus* constituted 94% of the total isolates of which *A. ruber* and *P. expansum* were the most common species. Other genera isolated included *Rhizopus*, *Cladosporium*, *Alternaria*, and *Trichothecium*. Although aflatoxins were not detectable on the original samples, 2/3 isolates of *A. flavus*, the most toxic species of *Aspergillus*, were aflatoxin producers. The presence of these quantities and types of mold on commercial shrimp samples could have public health implications. (23 refs)

79-0158 Production of Aflatoxins and Other Fluorescent Metabolites by Strains of *Aspergillus flavus* Isolated from Staple Foods and their Toxicity to Rats. (Eng) Angsubhakorn, S. (Dept. Pathobiology, Faculty Science, Mahidol Univ., Bangkok, Thailand); Bhamarapavati, N.; Romruen, K.; Phienpichit, L.; Thamavit, W.; Sahaphong, S. *Food Cosmet Toxicol* 16(5): 427-430; 1978.

The toxicity of 40 strains of *Aspergillus flavus* isolated from food marketed in Thailand between 1967 and 1969 was examined. Approx 92% of the strains produced aflatoxins B₁ and B₂. Acute toxicity tests in weanling Wistar rats showed that 87.5% of chloroform-extract fractions administered po caused at least one death in test groups of five rats, compared with 38% of petroleum ether-insoluble fractions administered ip. Both fractions produced similar histopathologic lesions in surviving rats. Unidentified compounds that were produced by 18 *A. flavus* strains may have modified the toxic effect of the aflatoxins. (7 refs)

79-0159 Effect of Various Glycolytic and TCA Intermediates on Aflatoxin Production. (Eng) Buchanan, R. L. (Dept. Nutrition and Foods, Drexel Univ., Philadelphia, PA, 19104); Ayres, J. C. *J Food Safety* 1(1): 19-28; 1977.

The effect of various exogenously supplying tricarboxylic acid (TCA) and glycolytic intermediates on aflatoxin production by *Aspergillus parasiticus* was studied with the organism growing in synthetic and semi-synthetic media. At low concentrations, glycerol, lactate, and pyruvate stimulated aflatoxin production in the synthetic medium. At high con-

centrations, pyruvate, citrate, alpha-keto glutarate, fumarate, and malate inhibited aflatoxin accumulation in both media. All supplements except glycerol stimulated sporulation and elevated the pH of the cultures. (12 refs)

- 79-0160 Mutagenicity to *Salmonella typhimurium* of Some *Aspergillus* and *Penicillium* Mycotoxins.** (Eng) Wehner, F. C. (Natl. Res. Inst. Nutritional Diseases South African Medical Res. Council, Tygerberg 7505, South Africa); Thiel, P. G.; Van Rensburg, S. J.; Demasius, I. P. *Mutat Res* 58(2/3): 193-203; 1978.

The mutagenic activity of 17 mycotoxins produced by *Aspergillus* and *Penicillium* species was tested in the Ames' assay using *Salmonella typhimurium* strains, TA98, TA100, TA1535, and TA1537, both with and without a rat liver microsome fraction (S-9) prepared from Aroclor-1254-injected male Wistar-derived rats. The concentrations of the mycotoxins used were determined by preliminary trials and availability. The positive controls aflatoxin B₁, sterigmatocystin and versicolorin A were all mutagenic in the presence of S-9 mix, as were viridicatumtoxin, kojic acid, austocystin A, austocystin D, and austdiol. Austdiol was also mutagenic without rat liver microsome activation. No mutagenic activity was noted for TR₂-toxin, secalonic acid D, penicillic acid, patulin, ochratoxin A, mycophenolic acid, O-methylsterigmatocystin, luteoskyrin, griseofulvin, fumitremorgen B, cyclopiazonic acid, or citrinin. Mutagenic potential seemed to be related to chemical structure, particularly the presence of the bisfuran ring, the xanthone group, and the gamma-pyrone moiety. In general, good agreement was found between existing data on carcinogenicity and mutagenicity determined here, although the carcinogens griseofulvin, luteoskyrin, patulin, and penicillic acid were not mutagenic in this assay. Due to the differing concentrations used, quantitative comparisons of the mutagenic properties of these mycotoxins cannot be made from this study. (46 refs)

- 79-0161 Cell Specificity in Metabolic Activation of Aflatoxin B₁ and Benzo(a)pyrene to Mutagens for Mammalian Cells.** (Eng) Langenbach, R. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Freed, H. J.; Raveh, D.; Huberman, E. *Nature* 276(5685): 277-280; 1978.

The abilities of rat liver cells and rat fibroblasts to metabolize benzo(a)pyrene (BP) and aflatoxin B₁ (AFB₁) to water-soluble products, to intermediates that bind to cellular DNA, and to intermediates that are mutagenic to Chinese hamster V79 cells were studied. BP caused a 17- to 55-fold increase in mutation frequency in V79 cells cocultivated with fibroblasts but no increase in this frequency in V79 cells cocultivated with hepatocytes. AFB₁ caused a 10- to 40-fold increase in mutation frequency in V79 cells cocultivated with hepatocytes and a 2-fold increase in mutation frequency in V79 cells cocultivated with fibroblasts. Hepatocytes metabolized BP

and AFB₁ to water-soluble products, while fibroblasts metabolized BP but not AFB₁. After 24 hr exposure to BP (1 µg/ml), approx three times as much BP was bound to the DNA of the fibroblasts as was bound to the DNA of the liver cells. The data indicate that a cell-type specificity in chemical carcinogenesis can be investigated by the cell-mediated assay and that overall metabolism alone is not sufficient to predict the activity of a carcinogen in a given cell type. (25 refs)

- 79-0162 Improved Colorimetric Method for Determining Nitrate and Nitrite in Foods.** (Eng) Sen, N. P. (Health and Welfare Canada, Food Res. Div., Health Protection Branch, Ottawa, Ontario, Canada K1A 0L2); Donaldson, B. *J Assoc Off Anal Chem* 61(6): 1389-1394; 1978.

A method for determining nitrate and nitrite in cured meat products, cheeses, and vegetables is described. Nitrite is determined colorimetrically by diazotization of sulfanilic acid and subsequent coupling of the product with N-(1-naphthyl)-ethylenediamine. Nitrate is reduced to nitrite on a Cd column and determined similarly. The av recovery of 10-30 ppm of added sodium nitrite was 95%, that of 30-400 ppm of added sodium nitrate 94%. (20 refs)

- 79-0163 Strain Differences in Susceptibility of Rat Colon to 1,2-Dimethylhydrazine Carcinogenesis.** (Eng) Takizawa, S. (Dept. Cancer Res., Res. Inst. Nuclear Medicine and Biology, Hiroshima Univ., Kasumi 1-2-3, Hiroshima 734, Japan); Watanabe, H.; Naito, Y.; Terada, Y.; Fujii, I.; Hirose, F. *Gann* 69(5): 719-722; 1978.

Susceptibility to 1,2-dimethylhydrazine (DMH) carcinogenesis was compared in two rat strains, Wistar-Furth (WF) rats derived from a substrain prone to colon cancer and Long-Evans (LE) rats. Ten-week-old rats were injected with 20 mg/kg DMH weekly for 20 wk and sacrificed at weeks 10, 15, 20, and 25 after the last injection. The incidence of benign and malignant colon tumors and the number of tumors per rat were higher in LE rats. Most of the colon tumors occurred in the descending colon, where only a few tumors were found in WF rats. Autoradiographic studies did not show any apparent difference between the two rat strains (both DMH-treated and untreated controls) in the number of ³H-thymidine-labeled cells or in the number of mitotic cells in the mucosa of the descending colon. It is likely that a resistant rat strain (WF) for DMH carcinogenesis has emerged. (11 refs)

- 79-0164 Metabolism of Hydrazines and Hydrazides by the Intestinal Microflora.** (Eng) Bolton, G. C. (Dept. Biochemistry, Univ. Birmingham, Birmingham B15 2TT, England); Griffiths, L. A. *Experientia* 34(11): 1484-1486; 1978.

The ability of rat intestinal microflora to degrade a number of hydrazines and hydrazides during anaerobic incubation in vitro was examined. Medium containing 0.36 mg/ml hydrazo-substituted compound and microflora was incubated for 7 days and the inoculated media centrifuged. The supernatants were filtered and submitted either directly or following a dansylation reaction to thin-layer chromatography. All of the hydrazine compounds gave rise, by reductive fission, to primary amines. The hydrazides apparently did not undergo reductive fission, since none of the expected fission products were detected. There was no evidence of the formation of hydrazide hydrolysis products. These experiments indicate that under in vitro conditions, intestinal microflora is able to effect extensive reductive fission of hydrazines, but the extent to which this would occur in vivo must be assessed by studies in intact animals. (16 refs)

- 79-0165** Mutagenic Activity of Furfural in *Salmonella typhimurium* TA100. (Eng) Zdzienicka, M. (Dept. Biochemistry, Warsaw Medical Sch., Banacha 1, 02-097, Warsaw, Poland); Tudek, B.; Zielenska, M.; Szymczyk, T. *Mutat Res* 58(2/3): 205-209; 1978.

The mutagenicity of furfural, a widely used solvent, was tested in the Ames' mutagenicity assay using *Salmonella typhimurium* strains TA100 and TA98, both with and without liver microsome S-9 mix prepared from Aroclor-1254-treated Wistar rats. Furfural was mutagenic in the TA100 strain: as a dose of 7 μ l/plate doubled the number of revertants; however, doses > 7 μ l/plate decreased the number of revertant colonies, due to the appreciable cellular toxicity of furfural. In fact, when toxicity was taken into account, the number of revertant colonies, per 10⁶ surviving cells was increased nine times by 7 μ l furfural. Furfural was not mutagenic toward strain TA98, and did not appear to be metabolically activated by the microsomal fraction of the rat liver. Because of suspected co-carcinogen activity, furfural was assayed with TA100 in the presence of 5 μ g/plate benzo(a)pyrene (BP). Although cellular toxicity was decreased, the curves for mutagenesis by furfural in the presence and absence of BP were similar, indicating that the mutagenic activity of furfural was not increased by the presence of BP. (8 refs)

- 79-0166** Mutagenic Effects of Thioacetamide in *Drosophila melanogaster*. (Eng) Magnusson, J. (Environmental Toxicology Unit, Wallenberg Lab., Univ. Stockholm, Stockholm, Sweden); Ramel, C. *Mutat Res* 58(2/3): 259-262; 1978.

The mutagenicity of thioacetamide was tested in *Drosophila melanogaster*. Thioacetamide was administered to 2-day old males either intra-abdominally (500 ppm or 100 ppm) or po (2,500 ppm). After treatment the males were individually mated and mutagenicity determined by the sex-linked recessive lethal test in heterozygous daughters from this mating.

In all three experiments there was a significant increase of lethals in the thioacetamide-treated series compared with controls. The different dosages used in the injection experiments did not reveal any dose-effect relationship for mutagenicity; the frequency of lethals was lower with the higher than with the lower dose (0.19% and 0.28%, respectively). In the feeding experiment, the percentage of lethals was 0.22% compared to 0.05% for controls. It is concluded that thioacetamide is a mutagen, a result that correlates with its carcinogenicity in mice and rats. (14 refs)

- 79-0167** Mitogenic and Carcinogenic Effects of a Hypolipidemic Peroxisome Proliferator, [4-Chloro-6-(2,3-xylidino)-2-pyrimidinylthio]acetic Acid (Wy-14,643), in Rat and Mouse Liver. (Eng) Reddy, J. K. (G. D. Searle & Co., P. O. Box 5110, Chicago, IL, 60680); Rao, M. S.; Azarnoff, D. L.; Sell, S. *Cancer Res* 39(1): 152-161; 1979.

The effects of [4-chloro-6-(2,3-xylidino)-2-pyrimidinylthio]-acetic acid (Wy-14,643), a potent hepatic peroxisome proliferator, on male acatalasemic CS-b mice and F344 rats were investigated. Wy-14,643 was incorporated in the diet at a level of 0.1% for 16 mo (15 rats) or at a level of 0.1% for 6 mo and then 0.05% for 8.5 mo (20 mice). All 18 surviving mice developed multiple liver tumors, most of which were of the trabecular type. Vascular invasion was encountered frequently in these tumors. All 15 rats developed hepatocellular carcinomas with trabecular patterns. Metastases to the lungs were present in five mice and six rats. Peroxisomes were prominent in the tumors, and several of these organelles contained prominent nucleoids. The carnitine acetyltransferase activity in the primary hepatocellular carcinomas was markedly increased, but catalase activity in the tumors was not inducible. In a short-term study, liver wt, liver DNA, and specific radioactivity of labeled DNA increased in rats fed 0.125% Wy-14,643 for 5 days. There was no evidence of hepatocellular necrosis. Elevations in serum alpha-feto-protein concentration were associated with and proportional to liver cell proliferation. The data prompt concern over the potential carcinogenicity of hepatic peroxisome proliferators as a class. (52 refs)

- 79-0168** Interaction of Glyoxal with Glycine and N-Methylacetamide: Some Aspects of Their Potential Energy Surface and Its Relation with Cancer. (Eng) Del Conde, G. (Division de Estudios Superiores, Facultad de Quimica, Universidad Nacional Autonoma de Mexico, Mexico 20, D.F.); Estrada, M.; Cardenas, A. *Int J Quant Chem Quant Biol Symp* (5): 393-401; 1978.

The interactions of cis- and trans-glyoxal and glycine as a prototype of the carboxylic end of a protein, and the interaction of glyoxal and N-methylacetamide as a prototype of a peptide bond were investigated. Part of their potential energy

surface was obtained by the CNDO/2 approximation. The action of trans- and cis-glyoxal was shown to be completely different in a model of a carboxylic end of a protein, suggesting that cis-glyoxal should not have any effect as a "brake" in protein biosynthesis. Analysis of a peptide-bond model suggested that both glyoxal isomers should behave in a similar way. (9 refs)

79-0169 Inhibition of In Vitro Metabolic Activation of Carcinogens by Wheat Sprout Extracts. (Eng)

Lai, C. N. (Dept. Biology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77025); Dabney, B. J.; Shaw, C. R. *Nutr and Cancer* 1(1): 27-30; 1978.

When tested in the Ames' mutagenicity assay with *Salmonella typhimurium* strain TA100 and S-9 rat liver homogenate fraction, extracts from the leaves and roots of 7- to 14-day-old wheat sprouts were able to inhibit the mutagenicity of 2-acetylaminofluorene (50 µg/plate), N-hydroxy-2-acetylaminofluorene (5 µg), 3-methylcholanthrene (25 µg), 2-aminoanthracene (0.3 µg), benzo(a)pyrene (BP: 5 µg), and aflatoxin B₁ (0.1 µg), compounds known to require metabolic activation. The degree of mutagenic inhibition was dependent upon the dose of sprout extract (25-150 µl). Carcinogens that do not require metabolic activation (2-nitrofluorene, ethyl methanesulfonate, and N-methyl-N'-nitro-N-nitrosoguanidine) were not inhibited by sprout extracts. High-pressure liquid chromatographic profiles of the BP metabolites showed that dihydrodiols were reduced significantly, particularly by the root extracts. Mung bean and lentil sprouts demonstrated inhibition similar to that of the wheat sprouts. Analysis of the wheat sprouts suggested that the active component is a heat-sensitive protein or protein-bound entity with a mol wt > 100,000. The extracts were inhibitory at relatively low levels and they were nontoxic, even at high levels, unlike most other known mutagenicity inhibitors. (24 refs)

79-0170 Structural Evidence on DNA Carcinogen Interactions. N-Acetoxy-2-acetylaminofluorene Binding to DNA. (Eng)

Norden, B. (Dept. Inorganic Chemistry, Univ. Lund, Chemical Center, P.O. Box 740, S-220 07 Lund, Sweden). *Biophys Chem* 8(4): 385-391; 1978.

The interaction between N-acetoxy-2-acetylaminofluorene (AAAF) and calf thymus DNA was studied by a linear dichroism (LD) measuring technique. In a low-ionic-strength 50% methanol solvent at room temperature, only a weak complex (van der Waals) appeared. However, when a "sodium-free" sample was heated to < 40 C, strand separation was observed and a covalent aminofluorene complex formed. After the sample was cooled to room temperature, a characteristic positive LD band was observed at 306 nanometers (nm). The temperature effect was clearly related to denaturation or par-

tial denaturation. The average angular orientation of the long axis of the fluorene moiety (47 degrees to the local helix axis) was inconsistent with intercalation. It could be explained by a free rotation around a C(DNA)-N(aminofluorene) bond or by a major groove site. The occupation density was 1 to 2 aminofluorene residues per 100 bases. With native DNA, AAAF slowly formed a covalent complex that had a negative LD at 307 nm. The orientation (70-90 degrees) was consistent with steric direction by the strand. (17 refs)

79-0171 Sister-Chromatid Exchanges Induced in Rabbit Lymphocytes by 2-Aminofluorene and 2-Acetylaminofluorene after In Vitro and In Vivo Metabolic Activation. (Eng)

Takehisa, S. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143); Wolff, S. *Mutat Res* 58(2/3): 321-329; 1978.

The sister-chromatid exchanges (SCE) induced in rabbit peripheral lymphocytes by 2-aminofluorene (2-AF) and 2-acetylaminofluorene (2-AAF) were examined after in vivo and in vitro metabolic activation. Female New Zealand rabbits received (7, 50, or 200 mg/kg ip) or 2-AAF (3, 10, 50, 100, or 200 mg/kg ip) and blood was drawn for culture 1, 2, 3, and 7 days later. In rabbits injected with 2-AF, a transient dose-dependent increase in SCE was seen in peripheral lymphocytes cultured after stimulation with phytohemagglutinin (PHA). With 2-AAF, the response was more variable: some rabbits showed an increase in SCE immediately, but one showed an increase only after a subsequent injection. For the in vitro tests, blood drawn from three rabbits before they had received any injections was treated with the test chemicals and S-9 mix (rat-liver microsomes supplemented with an NADPH-generating system) for 30 min either just before culturing in PHA-containing medium or before addition of bromodeoxyuridine (BrdUrd). With 2-AF and S-9 mix treatment, there was no increase in SCE frequency unless the treatment occurred after PHA stimulation. Exposure for 30 min to 2-AAF and the metabolic activation system did not increase the yield of SCE at any time of culture. However, prolonged exposure of the cells to 2-AF or 2-AAF alone during the period of BrdUrd incubation after PHA stimulation increased the number of SCE. These results indicate that the addition of PHA and the consequent metabolic activation do affect the induction of enzymes involved in the activation of 2-AF and 2-AAF. (21 refs)

79-0172 Studies on the Mutagenicity of N-Hydroxy-2-acetylaminofluorene in the Ames-Salmonella Mutagenesis Test System. (Eng)

Andrews, L. S. (Pharmacology-Toxicology Program, Natl. Inst. General Medical Sciences, NIH, Bethesda, MD, 20014); Hinson, J. A.; Gillette, J. R. *Biochem Pharmacol* 27(20): 2399-2408; 1978.

N-hydroxy-2-acetylaminofluorene (NOH-2AAF) was

deacetylated by Sephadex G-25-chromatographed postmitochondrial supernatant fraction to a substance (presumably N-hydroxy-2-aminofluorene) that was a potent frameshift mutagen in the Ames-Salmonella tester strain TA1538. Preincubation of the supernatant fraction with paraoxon decreased the observed mutagenesis; however, the addition of several reducing agents or nucleophiles to the incubations did not alter the mutagenic response. Sulfation of NOH-2AAF decreased the mutagenesis observed under conditions of supernatant activation and increased the covalent binding of [¹⁴C-acetyl]NOH-2AAF to protein. Under conditions of N-O-sulfate ester generation, ascorbate or reduced pyridine nucleotides greatly increased the number of revertant colonies. Ascorbate did not alter the rate of sulfation of NOH-2AAF, but it decreased the protein covalent binding and greatly increased the reduction of the arylating species to 2-acetylaminofluorene (2AAF). Since 2AAF was not mutagenic under these conditions, the data are consistent with the concept of a free radical of 2AAF as the mutagenic intermediate. (32 refs)

79-0173 A Sub-population of Rat Liver Membrane-bound Ribosomes That are Detached In Vitro by Carcinogens and Centrifugation. (Eng) Palmer, D. N. (Dept. Biochemistry, Univ. Coll. London, Gower St., London WC1E 6BT, England); Rabin, B. R.; Williams, D. J. *Biochem J* 176(1): 9-14; 1978.

The chemical-carcinogen-induced detachment of ribosomes from Sprague-Dawley rat liver endoplasmic reticulum was studied in vitro. Incubation of postmitochondrial supernatant with 0.2 mM diethylnitrosamine or N-2-acetylaminofluorene removed approx 16% of membrane-bound ribosomes, measured as differences in RNA/protein values of membrane separated from unbound ribosomes by flotation. These ribosomes are also detached by exposure to high centrifugal forces (160,000 g) and are among those removed by NADPH-catalyzed lipid peroxidation. The ribosomes (polyribosomes) removed are not those detached from the membrane by exposure to high KCl concentrations (loosely bound) or high KCl concentrations in the presence of puromycin (tightly bound). It is concluded then that centrifugally labile and carcinogen-sensitive ribosomes represent a previously unreported subpopulation of membrane-bound ribosomes. (30 refs)

79-0174 Hematogenous Development of Rat Mature Granulocytic Leukemia. Distribution of Leukemic Foci in Vertebral Bodies. (Eng) Takayama, S. (Dept. Pathology, Faculty Medicine, Tokyo Medical and Dental Univ., Tokyo, Japan); Fujiwara, M. *Acta Pathol Jpn* 28(5): 663-668; 1978.

The distribution of leukemic foci in the vertebrae of Wistar rats with N,N'-2,7-fluorenylenebisacetamide (2,7-FAA)-in-

duced or transplanted leukemias was studied. The leukemic foci in the bone marrow were small, circumscribed, and nodular, and there was little or no leukemic infiltration of the spleen or liver. In both the induced and transplanted leukemias, the leukemic foci were most frequently located around the center of the craniocaudal axis, but they were distributed evenly along the dorsoventral axis. The similar infiltration patterns of the 2,7-FAA-induced and transplanted leukemias suggests a similar mode of spread. 2,7-FAA-induced mature granulocytic leukemia may be spread by hematogenous metastasis from primary nodular foci in the bone marrow to other parts of the bone marrow. (13 refs)

79-0175 Rat Liver Aldehyde Dehydrogenase--Immunochemical Identity of 2,3,7,8-Tetrachlorodibenzo-p-dioxin Inducible Normal Liver and 2-Acetylaminofluorene Inducible Hepatoma Isozymes. (Eng) Lindahl, R. (Developmental Biology Section, Dept. Biology, Univ. Alabama, University, AL, 35486); Roper, M.; Deitrich, R. A. *Biochem Pharmacol* 27(20): 2463-2465; 1978.

Aldehyde dehydrogenase (ALDH) isozymes in 2-acetylaminofluorene-induced rat hepatomas were studied immunochemically. In Ouchterlony immunodiffusion assays, rabbit antisera against 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)-induced normal liver ALDH α and τ isozymes formed precipitin lines with hepatoma-specific α isozymes. Hepatoma-specific antibody against hepatoma-specific α isozyme reacted with complete identity with normal liver TCDD-induced τ isozyme. Neither anti- α nor anti- τ serum reacted with phenobarbital-induced rat liver ALDH ϕ isozyme. Thus, the α and τ isozymes are not related immunochemically to the ϕ isozyme. (21 refs)

79-0176 Growth Stimulation Following Serum Transfer from Carcinogen-treated Donors to Normal Rats: a New Aspect of Early Carcinogen Actions. (Eng) Danz, M. (Pathologisches Institut, Friedrich-Schiller-Universität, Ziegmühlenweg 1, DDR-69 Jena, E. Germany); Urban, H.; Brauer, R.; Schmidt, A. *Exp Pathol (Jena)* 16(1-6): 23-35; 1978.

The effects of treatment with 2-acetylaminofluorene (AAF, 120 mg/kg by stomach tube) or with the serum of AAF-treated animals (1.5 ml/g) on growth of the liver, adrenals, esophageal epithelium, and jejunal crypts were studied in male Sprague-Dawley rats. Serum was taken from AAF-treated donors sacrificed 9, 14, or 24 hr after treatment. Liver wts were elevated in rats treated with serum taken 9 or 14 hr after AAF treatment. A mild inflammatory response in the portal fields was seen 24 hr after AAF treatment, but there were no abnormalities in animals treated with serum. The hepatic mitotic index decreased significantly with time in the AAF-treated rats and increased significantly in serum-treat-

ed rats, especially at 28 hr after injection. The adrenal mitotic index was decreased 14 hr after AAF treatment and was increased after serum treatment. The stimulatory activity of the serum was limited to the outer and middle layers of the zona fasciculata of the adrenal cortex. The mitotic indices of the esophageal epithelium and jejunal crypts were not influenced by AAF or serum treatment. Serum from AAF-treated animals had an in vitro stimulatory effect on thymocytes. (66 refs)

- 79-0177 Morphometric Investigations on Endocrine Glands. IV. The Rat Thyroid During Liver Regeneration after Partial Hepatectomy with and Without Application of Carcinogenic Substances.** (Eng) Low, O. (Pathologisches Institut, Friedrich-Schiller-Universitat, DDR-69 Jena, Zieglmuhlenweg 1, E. Germany); Richter, S.; Franke, I.; Danz, M. *Exp Pathol (Jena)* 16(1-6): 234-244; 1978.

Histologic changes in the thyroid gland during regeneration after partial hepatectomy and the effects of pretreatment with acetylaminofluorene (AAF, 55 mg/kg/day for 3 days) or methylnitrosourea (MNU, 12 mg/kg/day for 3 days) were studied using male Wistar and Sprague-Dawley rats. The thyroids of laparotomized controls histologically resembled those of untreated rats. Those of hepatectomized rats were characterized by follicles that were reduced in size and contained less colloid. The relative percentages of epithelium increased by day 3 after hepatectomy and were particularly marked by day 10. The percentage of mitoses was lower than that in controls. AAF decreased the relative amount of thyroid epithelium before and after hepatectomy and increased the relative amount of colloid. MNU had a similar effect when followed by hepatectomy, but it had no effect alone. The results suggest that regeneration resulted in activation of the thyroid and that thyroid hormones may influence carcinogenesis and vice versa. (74 refs)

- 79-0178 Nitrite Formation from 2-Nitropropane by Microsomal Monooxygenases.** (Eng) Ullrich, V. (Dept. Physiological Chemistry, Physiologisch-chemisches Institut, Universitat des Saarlandes, 665 Homburg-Saar, W. Germany); Hermann, G.; Weber, P. *Biochem Pharmacol* 27(19): 2301-2304; 1978.

In the presence of NADPH and dioxygen, Sprague-Dawley rat liver microsomes catalyzed the oxidative denitrification of 2-nitropropane to acetone and nitrite. Pretreatment of the animals with phenobarbital and 3-methylcholanthrene increased the specific activity. Inhibitors of microsomal monooxygenases inhibited nitrite formation, and the photochemical action spectrum of the CO-inhibited reaction indicated the involvement of cytochrome P450. The Km value and the spectral dissociation constant, Ks, of the substrate binding spectrum were both around 10^{-2} M. 1-Nitropropane

also undergoes oxidative denitrification. It is suggested that aliphatic nitro compounds may have mutagenic or carcinogenic effects, as recently demonstrated for 2-nitropropane in rats. (21 refs)

- 79-0179 Determination of Radiation Equivalence of the Chemical Furfurylamine (AF-2) for the Induction of Gene Conversion in Diploid Yeast and Estimation of Genetic Risk to the Japanese Population.** (Eng) Murthy, M. S. (Div. Radiological Protection, Bhabha Atomic Res. Centre, Trombay, Bombay-400 085, India); Sankaranarayanan, N. *Mutat Res* 54(3): 323-331; 1978.

Dose-effect relationships for the induction of gene conversion by furfurylamine (AF-2) in diploid yeast were established and used to determine the radiation equivalence (rec) value for AF-2 and the genetic risk to the Japanese population arising from its consumption. The rec value, calculated by taking the ratio of the slopes of the dose-effect curves to gamma radiation to that of AF-2, was determined to be $0.085 \mu\text{g/ml/hr}$. This value was remarkably consistent with the rec values previously obtained in different test systems and with different end-points. The genetic burden to the Japanese population due to consumption of AF-2 was estimated to be equivalent to 55 millirec. However, uncertainties in the consumption of AF-2 per person and in its metabolic detoxification tend to lower the probable value to a small fraction of that due to natural background ionizing radiation (average, 100 mrem/yr). - 79-0180 Chromosome Breakage and Neoplastic Transformation of Syrian Golden Hamster Embryonic Cells in Tissue Culture by Transplacental Application of 2-(2-Furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2).** (Eng) Inui, N. (Section Cell Biology, Cytogenetics, Biological Res. Inst., Japan Tobacco and Salt Public Corporation, Hatano, Kanagawa 257, Japan); Nishi, Y.; Taketomi, M. *Mutat Res* 58(2/3): 331-338; 1978.

On day 11 or 12 of gestation, Syrian golden hamsters were injected ip with 0.5 ml dimethyl sulfoxide containing 20, 50, or 100 mg/kg 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2). Embryos were isolated 24 hr later, cultured, and examined for the carcinogenic and mutagenic effects of transplacental exposure to AF-2. Within the first 24 hr of primary culture, cells were treated with colcemide for 3 hr so that mitotic cells could be observed in the first cell cycle in vitro. Cultured embryonic fibroblasts in metaphase plates showed a marked dose-dependence in chromosome aberrations. Transplacental application of AF-2 also caused a slightly dose-dependent morphological transformation. When transformed colonies were cloned and transferred to the hamster cheek pouch, these cells produced tumors in the host animals. This new in vivo-in vitro combination assay system should

be useful in detecting potential environmental carcinogens. (26 refs)

- 79-0181** Determination of Ethanolamines and N-Nitrosodiethanolamine in Commercial Cutting Fluids by Gas Chromatography and Mass Fragmentography. (Jpn) Kawano, M. (Dept. Environmental Conservation, Coll. Agriculture, Ehime Univ., 3-5-7, Tarumi, Matsuyama-shi, Ehime, Japan); Wakimoto, T.; Tatsukawa, R. *Bunseki Kagaku* 27(10): 616-621; 1978.

A method for simultaneous determination of ethanolamines and N-nitrosodiethanolamine (ND) in commercial cutting fluids was developed. A sample (about 10 mg) is taken into a test tube with a cap and then ethanol (1 ml), urea (2%, 0.5 ml), and acetic acid (0.1 ml) are added to destroy the nitrite that is usually present in a sample. After being shaken slowly, the mixture is dried by heating under a stream of nitrogen gas. Ethanol (about 1 ml) is added to the residue, which is dried until it does not smell of acetic acid, and is silylated in an oil bath for 10 min with dimethylformamide (200 μ l) and N,O-bis(trimethylsilyl)trifluoroacetamide (200 μ l) at 60 C. The silylated soln is diluted with dimethylchloride, and an aliquot is injected into the gas chromatograph. Some selected mass numbers (mass/electric charge) of ethanolamines (mono, di, and tri) and ND are 102, 130, 262, and 130. Through the analytical process, artifact formation of ND was not observed. The detection limit for ethanolamines (mono, di, and tri) and ND by mass fragmentography were 1, 1, 1, and 5 nanog, and by gas chromatography were 4, 2, 2, and 4 μ g, respectively. (8 refs)

- 79-0182** A Possible Short-Term Prediction of Potential Carcinogenicity of Chemical Compounds In Vivo by Means of a Promoting Activity Test (PAT). (Eng) Danz, M. (Pathologisches Institut, Friedrich-Schiller-Universitat, DDR-69 Jena, Ziegmuhlenweg 1, E. Germany); Urban, H.; Schmidt, A.; Ziebarth, D. *Exp Pathol (Jena)* 16(1-6): 109-120; 1978.

Carcinogens of chemically unrelated structure and different organotropism stimulated mitosis in the adrenocortical cells of Sprague-Dawley and Wistar rats and Syrian golden hamsters in vivo. The animals were given a single dose of approx 15%-30% of the LD₅₀ of each substance, mainly by stomach tube, and sacrificed 48 hr later. A similar response was observed in the regenerating liver of rats following partial hepatectomy or intoxication by carbon tetrachloride. This relatively rapid response was probably due to the emergence of humoral growth stimulators that are evidenced in restorative regeneration, and it probably accounts for the promoting activity of carcinogens. Special problems resulting from false-positive (indomethacin, sodium nitrite) and false-negative (7,12-dimethylbenz(a)anthracene, ethionine) findings as well as the role of solvents are discussed. The agreement be-

tween the results of this short-term test and long-term carcinogenicity tests of trinitrosotrimethylenetriamine, nitrosoethyl-tert-butylamine, and nitrosodiallylamine illustrates the accuracy of the former for predicting the carcinogenicity of chemical compounds. (65 refs)

- 79-0183** Enhancing Effect of Partial Pancreatectomy and Ethionine-induced Pancreatic Regeneration on the Tumorigenesis of Azaserine in Rats. (Eng) Denda, A. (Dept. Oncological Pathology, Cancer Center, Nara Medical Univ., 840 Shijo-cho, Kashihara, Nara-ken 634, Japan); Inui, S.; Sunagawa, M.; Takahashi, S.; Konishi, Y. *Gann* 69(5): 633-639; 1978.

The effect of partial pancreatectomy (PP) or a protein-deficient diet containing 0.5% ethionine (ethionine diet: ED) on the pancreatic tumorigenesis of azaserine (AZ) was studied in Wistar rats. Adenomas of the nonendocrine pancreas were induced in 100% of rats in all AZ-treated groups at 62 wk. The size and number of the adenomas were significantly increased in rats of the PP and ED groups, compared with those in the control group. Although there was no significant difference in the number of adenomas in rats treated by PP pancreatectomy and those given the ED, the size of the tumors was significantly larger in the PP rats than in the ED rats. These results indicate that pancreatic tumorigenesis by AZ was enhanced by both the regeneration induced by PP and the ingestion of the ED; however, the enhancing effect of PP was greater than that of the ED. (23 refs)

- 79-0184** In Vivo Autoradiography and Nitrosoheptamethyleneimine Carcinogenesis in Hamsters. (Eng) Reznik-Schuller, H. (Chemical Carcinogenesis Program, NCI-Frederick Cancer Res. Center, Frederick, MD, 21501); Lijinsky, W. *Cancer Res* 39(1): 72-74; 1979.

This study is part of a series of morphological and biochemical investigations of the pronounced organotropic effects of some nitrosamines. Quantitative autoradiograms were made, in vivo, in European hamsters with the use of a single dose of [¹⁴C]nitrosoheptamethyleneimine (NHMI: 260 μ Ci/animal; time between intragastric administration of nitrosamine and killing of animals, 6 hr). The animals had been given weekly sc injections of unlabeled NHMI at 0.20 of the dose lethal to 50% of the animals (33 mg/kg). In this species, the lung is the principal target, and radioactivity was found in the Clara cells of the bronchial epithelium and in the NHMI-induced tumors derived from these cells. Tumors were not induced in the liver, which can metabolize this compound, and labeling was found principally in the cytoplasm of liver cells. In the target cells, however, there was a high degree of labeling in both the cytoplasm and the nuclei. (12 refs)

- 79-0185 Electronic Structure of Biopolymers and Possible Mechanisms of Chemical Carcinogenesis.** (Eng) Ladik, J. (Lehrstuhl für Theoretische Chemie, Friedrich-Alexander-Universität Erlangen-Nürnberg, 8520 Erlangen, W. Germany); Suhai, S.; Seel, M. *Int J Quant Chem Quant Biol Symp* (5): 35-49; 1978.

The results of a coherent potential approximation calculation using k - and energy-dependent self-energy are presented for a polymer, namely, the (SN) x and (SN-H) x mixed system. In addition, band structures for polyglycine are presented. On the basis of information concerning the electronic structures of these biopolymers, possible mechanisms of action of different carcinogens bound to DNA and/or proteins are discussed. (42 refs)

- 79-0186 Conduction in Protein and Methylglyoxal-Protein Complexes.** (Eng) Lewis, T. J. (Univ. Coll. North Wales, Bangor, Gwynedd, Wales). *Int J Quant Chem Quant Biol Symp* (5): 149-158; 1978.

A model for the dielectric and conductive behavior of proteins and protein-methylglyoxal complexes based on thermally activated hopping (or charge carrier motion) is presented. It appears that this model gives a reasonable interpretation of a wide range of electrical measurements on the proteins, especially when they are complexed with methylglyoxal. (18 refs)

- 79-0187 Application of High Performance Liquid Chromatography for the Determination of N-Nitrosodialkylamines.** (Jpn.) Hirayama, T. (Kyoto Coll. Pharmacy, Misasagi, Yamashina-ku, Kyoto, Japan); Kiuchi, T.; Fukui, S. *Shokuhin Eiseigakuzasshi* 19(5): 468-473; 1978.

High performance liquid chromatography proved to be faster and easier than other methods for the determination of N-nitrosamines. Sensitivity was 0.05 nanog, and the recoveries of all but one of the N-nitrosamines tested (N-nitrosodimethylamine) were over 99%. (20 refs)

- 79-0188 Estimation of Extractable N-Nitroso Compounds at the Parts-per-Billion Level.** (Eng) Drescher, G. S. (Ciba-Geigy Corp., Development Dept., McIntosh, AL); Frank, C. W. *Anal Chem* 50(14): 2118-2121; 1978.

A rapid (< 1 hr) preliminary screening method for estimating the total N-nitroso group content in a wide variety of environmental samples is described. The samples are extracted with methylene chloride and back-extracted with distilled-deionized water to remove nitrite. The extract is dried over anhydrous sodium sulfate, concentrated, and subjected to

acid-catalyzed denitrosation using 0.2 ml of 0.56 M HBr in glacial acetic acid. The nitric oxide that evolves is detected via its chemiluminescence reaction with ozone. The detection limits are < 10 ppb for most N-nitroso compounds, which permits the use of original sample sizes as low as 10 g. The selectivity of the method is excellent, with the only serious interferences being due to sodium nitrite and alkyl nitrites, although their molar response values are considerably lower than those obtained for the same concentrations of N-nitroso derivatives. The detection system responds on an equimolar basis to a wide range of different N-nitroso compounds with a precision of $\pm 5\%$. Application of the method to 100-g samples of water, soil, and urine spiked with approx 1 μ of N-nitroso compound is described. (29 refs)

- 79-0189 Determination of Nitrite at Low Level Without Prior Extraction.** (Eng) Walters, C. L. (British Food Manufacturing Industries Res. Assoc., Leatherhead, Surrey, England); Downes, M. J.; Hart, R. J.; Perse, S.; Smith, P. L. *Z Lebensm Unters Forsch* 167(4): 229-232; 1978.

A procedure that permits the determination of low levels of sodium nitrite in food or other dried matrices without prior extraction is described. Nitric oxide released from nitrite through the action of acetic acid is determined by a chemiluminescence analyzer. The detection limit is approx 0.02 μ g. Although the method is most suitable for use with dry materials, the response from a wet sample could be monitored through subsequent injection of a standard aliquot of nitrite in a minimum volume of water. (10 refs)

- 79-0190 Effects of Cytochrome P-448 and P-450 Inducers on Microsomal Dimethylnitrosamine Demethylase Activity and the Capacity of Isolated Microsomes to Activate Dimethylnitrosamine to a Mutagen.** (Eng) Guttenplan, J. B. (Dept. Biochemistry, New York Univ. Coll. Dentistry, New York, NY, 10010); Garro, A. J.; Hutterer, F. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 139-153; 1977.

The relationship between dimethylnitrosamine demethylase (DMN DMase) and the activation of DMN mutagenicity was analyzed through the use of three types of microsomal enzyme inducers, phenobarbital (PB), 3-methylcholanthrene (3-MC), and Aroclor 1254. The microsomes were prepared from male C57 and DBA/2 mice. Activation of DMN to a mutagen was assayed by a bacterial auxotroph reversion test using the His- *Salmonella typhimurium* strain TA1530. Aminopyrine DMase and benzo(a)pyrene (BP) hydroxylase activities were also monitored as representative of enzymes that are primarily cytochrome P-450- and P-448-dependent,

respectively. With C57 mice, all three inducers produced significant increases in DMN DMase and mutagenic activities. The capacity of microsomes from all treated animals to convert DMN to a mutagen was increased to a greater extent than their capacity to demethylate DMN. With DBA/2 mice, 3-MC was ineffective; the response to PB was normal and that to Aroclor 1254 was reduced compared with the responses of C57 mice. SKF 525-A inhibited mutagenic activation and the enzyme activities of 3-MC induced and control microsomes, particularly the latter. BP was more effective in inhibiting mutagenic activation and the enzyme activities of 3-MC-induced and control microsomes, particularly the latter. In all cases, mutagenesis was inhibited to a greater extent than the enzyme activities. Cytochromes P-450 and P-448 may contribute to DMN DMase and mutagenicity, and high levels of both cytochromes may be necessary for efficient activation of DMN to a mutagen. (33 refs)

- 79-0191 The Phosphorylation of Rat Liver Ribosomes Following Administration of Dimethylnitrosamine.** (Eng) Gressner, A. M. (Dept. Clinical Chemistry, Medical Faculty RWTH, Aachen, W. Germany); Greiling, H. *Biochem Pharmacol* 27(21): 2495-2498; 1978.

The effect of dimethylnitrosamine (DMNA) administration on liver ribosomal protein phosphorylation was studied in male Sprague-Dawley rats. The animals were injected ip with 30 mg/kg DMNA and at 2 and 5 hr later with 0.8 mCi carrier-free (32 P)-orthophosphoric acid. The rats were killed 30 min later. The incorporation of (32 P)phosphate into the 40S ribosomal subunit was stimulated five- and nine-fold at 2 and 5 hr, respectively, after administration of the drug. The phosphorylation of the 60S ribosomal subunit was not affected. The enhanced phosphorylation of the 40S subunit was due to a 20-fold stimulated incorporation of phosphate into only one ribosomal protein, S6. The functional significance of this type of postsynthetic modification of the 40S subunit is difficult to assess since the role of protein S6 and of its phosphorylated derivative S6P in the mechanism of peptide chain synthesis is not clear. It is speculated that S6 and S6p may influence the selection of specific messenger RNAs by the 40S subunit and thus influence the qualitative regulation of protein synthesis on the translational level. - 79-0192 Somatic Crossing-Over in Glycine Max (L.) Merrill: Activation of Dimethyl Nitrosoamine by Plant Seed and Comparison with Methyl Nitrosoarea in Inducing Somatic Mosaicism.** (Eng) Arenaz, P. (Program in Genetics, Washington State Univ., Pullman, WA, 99163); Vig, B. K. *Mutat Res* 52(3): 367-380; 1978.

The potential of dimethylnitrosamine (DMN) to cause somatic mosaicism was studied in a *Glycine max* (soybean) test system and compared with that of methyl nitrosoarea (MNU). In this system, DMN was activated by plant seeds

to a true mutagen without the addition of NADPH or the S-9 fraction of rat liver homogenate. Mosaicism was induced with a dose as low as 1.25 ppm DMN, with the upper limit for spot production being reached at 60 ppm. MNU, which does not require activation, did not show a limitation. The frequency of twin spots on $Y_{11}y_{11}$ leaves was increased only slightly by DMN or MNU, suggesting a small increase in somatic crossing-over. Neither chemical could mutate y_{11} to Y_{11} . (35 refs)

- 79-0193 Inhibition of Rat Hepatic Dimethylnitrosamine Demethylase by Cyclic and Acyclic Nitrosamines and Secondary Amines.** (Eng) Chau, I. Y. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Archer, M. C. *Experientia* 34(11): 1505-1506; 1978.

The inhibition of hepatic dimethylnitrosamine (DMN) demethylase by a number of cyclic and acyclic nitrosamines and secondary amines was investigated using male albino Sprague-Dawley rats. The animals were pretreated for 7 days with 0.1% phenobarbital po and then sacrificed. Rat liver microsomes were incubated for 5 min before the addition of DMN (102 mM) and various concentrations of inhibitor. All of the nitrosamines examined, both acyclic and cyclic, produced a concentration-dependent inhibition of hepatic DMN metabolism. Nitrosopiperidine and nitrosodipropylamine were the most effective inhibitors. Nitrosopyrrolidine and diethylnitrosamine were also effective inhibitors, but nitrosomorpholine was only a weak inhibitor. Nitrosoproline, a noncarcinogenic nitrosamine, also inhibited DMN demethylase, but it exhibited a biphasic inhibition profile. Secondary amines corresponding to the nitrosamines studied inhibited DMN demethylase in a manner similar to the nitrosamines and in the same quantitative range. The similarity of the inhibition with the nitrosamines and the amines suggests that interaction of nitrosamines with DMN demethylase is largely determined by structural characteristics of the amine moiety. - 79-0194 Formation and Loss of Alkylated Purines from DNA of Hamster Liver after Administration of Dimethylnitrosamine.** (Eng) Stumpf, R. (Dept. Physiology, Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA, 17033); Margison, G. P.; Montesano, R.; Pegg, A. E. *Cancer Res* 39(1): 50-54; 1979.

The methylation of hamster liver DNA was studied as a function of dose of dimethylnitrosamine (DMN). 7-Methylguanine levels were proportional to DMN doses over the range 10 μ g/kg to 25 mg/kg when measured 5-24 hr after treatment. This product was lost from the DNA at a rate greater than expected from spontaneous depurination at neutral pH, suggesting that enzyme-catalyzed excision takes place. O⁶-Methylguanine (OMG) levels were not proportional to

doses over this range but were much lower than expected (based on 7-methylguanine levels) when measured 5-24 hr after DMN doses below 0.5 mg/kg. This result may be due to the presence of an enzyme capable of removing OMG from DNA efficiently, provided the methylation level is low. The presence of such an enzyme in hamster liver extracts was demonstrated by incubation of the extracts with methylated DNA. The extracts significantly decreased the content of OMG in acid-precipitable DNA. However, when DMN doses above 0.5 mg/kg were used, removal of OMG occurred much more slowly, and the capacity of hamster liver to carry out removal of OMG from DNA in vivo was considerably lower than that of rat liver. The possible relevance of these findings to the relative susceptibility of these species to liver cancer induction by single doses of DMN is discussed. (20 refs)

- 79-0195 On Determination of Safe Concentrations of Carcinogenic N-Nitrosamines in Water.** (Rus) Basieva, T. Kh. (Cancer Res. Center, Moscow, USSR); Mikhailovskii, N. Ia.; Il'nitskii, A. P.; Korolev, A. A. *Gig Sanit* (10): 28-34; 1978.

Based on the literature data concerning the carcinogenicity of N-nitrosamines for rats, an attempt was made to calculate the permissible concentration of N-diethylnitrosamine (DENA) in water. Computer analysis of the results of experiments on the carcinogenicity of po administration of DENA to rats showed that a daily dose of 0.007 mg/kg did not induce tumors. Extrapolation of these findings to humans shows that the maximal permissible dose would be 10 mg/kg/d (0.03 µg/liter/d). (11 refs)

- 79-0196 Temperature Effects During and After the Diethylnitrosamine Treatment on Liver Tumorigenesis in the Fish, *Oryzias latipes*.** (Eng) Kyono, Y. (Zoological Inst., Faculty Science, Univ. Tokyo, Tokyo 113, Japan). *Eur J Cancer* 14(10): 1093-1097; 1978.

Four groups of medaka (*Oryzias latipes*) were treated with diethylnitrosamine (DENA: 100 ppm in drinking water) for 8 wk. Two groups were kept at a high temperature (22-25°C) and two at a low temperature (5-6°C). After DENA treatment, one of the high-temperature groups was transferred to high-temperature normal tap water (H.H group) and another to low-temperature tap water (H.L group). L.H and L.L groups were derived similarly. At 8 and 12 wk after the beginning of the experiment, about 10 fish in each group were sacrificed for histological observation. Many tumor nodules were found in the livers of fish in the H.H and H.L groups, but the number and the size of the nodules were greater in the H.H group than in the H.L group. In contrast, no tumor nodules were observed in L.H and L.L groups that were treated with DENA at a low temperature. These results suggest

an appropriately high temperature is necessary for the formation and the growth of tumor nodules. (16 refs)

- 79-0197 Phospholipids of the Endoplasmic Reticulum Membranes in Normal Rat Liver and During Early Stages of Carcinogenesis.** (Rus) Berdinskikh, N. K. (Inst. Problem Oncology, Kiev, USSR); Sanina, O. L.; Mel'nikova, N. N. *Vopr Onkol* 24(10): 42-48; 1978.

The phospholipid content of endoplasmic reticulum of rat liver was examined in random-bred albino rats: group 1 received diethylnitrosamine (DENA; 0.06% in drinking water), group 2 received a noncarcinogenic analog of DENA, diethylamine (DEA; dose as before), and group 3 served as control. Within 1-4 wk of the initiation of the experiment, rats were sacrificed and the content of phospholipids in the membranes of the liver endoplasmic reticulum was assessed by thin layer chromatography. DENA-induced changes in the phospholipid content were detected in both fractions of the endoplasmic reticulum: the total phospholipid content in the granular reticulum showed a 2.5-fold decrease during the 1st wk, while the agranular reticulum showed a 75% increase in phospholipid content during the 3rd wk of the experiment. The phospholipid content in rats treated with DEA did not differ significantly from controls. (12 refs)

- 79-0198 Epithelial Differentiation of the Embryonic Hamster Trachea and Its Significance for Studies on Diethylnitrosamine Transplacental Carcinogenesis.** (Eng) Emura, M. (Lab. Cell Biology, Aichi Cancer Center Res. Inst., Nagoya 464, Japan); Mohr, U. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 1015-1031; 1977.

To investigate whether the susceptibility of cells to diethylnitrosamine is correlated to a certain differentiated state of the prenatal tracheal epithelia, Syrian golden hamsters received a single sc injection of 45 mg diethylnitrosamine (DEN)/kg on one of the 15 days of pregnancy. Fifteen groups of six pregnant females were treated; mothers and weaned offspring were observed until spontaneous death, necropsied, and examined histologically. Respiratory tumors were evident in offspring of animals treated on the last 4 days of gestation, reaching an incidence of 95% on day 15 (19/20 animals). Tumors in the larynx and trachea (squamous cell papillomas and papillary polyps) were most common, and tracheal tumors increased particularly the later the carcinogen was administered. Several adenocarcinomas and one squamous cell carcinoma of the nasal cavities and several pulmonary bronchiogenic adenomas were also found in the offspring. A high incidence of respiratory tract tumors also occurred in the

mothers. Histological examination of tracheal epithelium of fetal hamsters from untreated mothers revealed that this epithelium is composed of one layer of columnar cells until day 12 of gestation and then differentiates into luminal, basal, and mucous progenitor cells. Whereas chromatin was homogeneously dispersed in early development, on day 12 it began a progressive condensation. The total volume and functional competence of the endoplasmic reticulum increased during this time. The mitotic activity of the tracheal epithelia was inversely related to the incidence of tracheal tumors and the degree of epithelial differentiation. The results demonstrate a positive correlation between the ultrastructural features of developing tracheal epithelia and their biochemical capacity to metabolize DEN. (18 refs)

79-0199 Definition of Stages During Hepatocarcinogenesis in the Rat: Potential Application to the Evaluation of Initiating and Promoting Agents in the Environment. (Eng) Sirica, A. E. (McArdle Lab. Cancer Res., Medical Sch., Univ. Wisconsin, Madison, WI); Barsness, L.; Goldsworthy, T.; Pitot, H. C. *J Environ Pathol Toxicol* 2(1): 21-28; 1978.

Agents that initiate and promote rat hepatocarcinogenesis were evaluated by giving female Sprague-Dawley rats a single intragastric instillation of diethylnitrosamine (DEN; 10 mg/kg) 24 hr after partial hepatectomy (67%); 2 mo later, 0.05% phenobarbital feeding was started in some of the animals and continued for 6 mo. In animals treated with DEN + PB, the number of liver foci exhibiting an altered enzyme histochemistry was increased at least fivefold over those produced in liver by DEN alone. Seven of eight DEN + PB-treated rats developed hepatocellular carcinomas, whereas no such neoplasms were seen in animals treated with DEN alone. None of the five animals that received PB alone showed enzyme-altered foci or neoplastic lesions in their livers. Three enzyme markers (glucose-6-phosphatase, canalicular ATPase, and γ -glutamyl transpeptidase) were used to evaluate the phenotypes of the enzyme-altered foci. Seven phenotypes were delineated in livers of both the DEN-treated group and the group treated with DEN + PB, but the quantitative pattern of phenotypic heterogeneity was different in the two groups. These results support the existence of a two-stage mechanism of liver carcinogenesis and suggest an in vivo screening model that appears capable of distinguishing between initiating and promoting agents in hepatocarcinogenesis. (30 refs)

79-0200 Topical Nitrogen Mustard Induced Carcinogenesis. (Eng) Kravitz, P. H. (Sub-Section Dermatology, Brown Univ., Providence, RI, 02908); McDonald, C. J. *Acta Derm Venereol (Stockh)* 58(5): 421-425; 1978.

Two cases of mycosis fungoides (MF) complicated by the development of cutaneous squamous cell carcinomas (SCC)

following nitrogen mustard (NM) therapy are reported. A 64-yr-old woman with MF of 20 yr duration had applied topical NM (10 mg of powder diluted in 20 ml water and 20 ml propylene glycol) to her entire body, including her face, for an 8-hr period daily. After 7 yr, she developed a superficially invasive SCC of the anterior chest and invasive SCC of her cheeks. Prior to NM, she had been treated with electron beam therapy and systemic chemotherapeutic agents. The second patient, an 82-yr-old man with MF of 40 yr duration had applied NM daily for 3 hr when an infiltrating SCC on the left lower leg was discovered. He also had been treated previously with various chemotherapeutic agents. The carcinoma was treated with x-radiation. Subsequently, recurrent tumors developed at the original tumor site, left proximal thigh, and upper back. Long-term application of topical NM to the skin probably rendered both patients susceptible to the development of multiple SCC. However, the previous or cumulative effects of systemic chemotherapy cannot be discounted. The patients did not have clinical evidence of chronic solar damage at their tumor sites. The virulence of the SCC in the man may have been related to external stimuli (radiation) or to impaired delayed hypersensitivity. (17 refs)

79-0201 Volatile Nitrosamines in Normal Human Faeces. (Eng) Wang, T. (Ontario Cancer Inst., 500 Sherbourne St., Toronto, Ontario, Canada M4X 1K9); Kakizoe, T.; Dion, P.; Furrer R.; Varghese, A. J.; Bruce, W. R. *Nature* 276(5685): 280-281; 1978.

The presence of volatile nitrosamines in normal human feces was studied by gas-liquid chromatography and high-pressure liquid chromatography. Freeze-dried condensates of fecal samples showed several peaks attributed to nitroso compounds, the five major compounds being N-nitrosodimethylamine (NDMA: amount present in typical condensate, 0.04 $\mu\text{g/liter}$), N-nitrosodiethylamine (NDEA, 0.10 $\mu\text{g/liter}$), N-nitrosodibutylamine (NDBA, 0.08 $\mu\text{g/liter}$), N-nitrosopiperidine (NPPI, 0.08 $\mu\text{g/liter}$), and N-nitrosomorpholine (NMOR, 0.02 $\mu\text{g/liter}$). In addition, fecal samples were collected from 12 healthy volunteers, immediately extracted with dichloromethane, and analyzed chromatographically. NDMA (0.3-1.5 $\mu\text{g/kg}$) was found in 11 samples, NDEA (0.2-13 $\mu\text{g/kg}$) in 8 samples, NDBA (< 1 $\mu\text{g/kg}$) in 2 samples, and NPPI and NMOR (< 2 $\mu\text{g/kg}$) in 3 and 5 samples, respectively. Many levels were higher than those found in the freeze-dried condensates, presumably as a result of losses of the volatile compounds during freeze-drying. The source of the nitroso compounds in the feces has not been established, but it is likely that they are produced in the lower gastrointestinal tract. (26 refs)

79-0202 Differential Mutagenicity of N-Methyl-N-nitrosocarbamate Insecticides in *Escherichia coli* Strains Having Different DNA Repair Capacities. (Eng) Yoshikawa, K. (Dept. Microbiology, Natl. Inst. Hygienic

Sciences, Kamiyoga 1-18-1, Setagaya-ku, Tokyo, Japan); Uchino, H.; Kurata, H. *Mutat Res* 54(3): 283-288; 1978.

The lethal and mutagenic effects of 1-naphthyl N-methyl-N-nitrosocarbamate (NAC), 3-methylphenyl N-methyl-N-nitrosocarbamate (MTMC), and 3,4-dimethylphenyl N-methyl-N-nitrosocarbamate (MPMC) on four isogenic strains of *Escherichia coli* having the same auxotrophic marker (arg⁻ Fam) were studied. Strains R15 (defective in the DNA polymerase I) and NG30 (recombination deficient) were more sensitive to killing by NAC, MTMC, and MPMC than were strains H/r30R (wild-type) and Hs30R (excisionless). Strains R15, H/r30R, and Hs30R showed similar susceptibility to the mutagenic effects of NAC, MTMC, and MPMC and were 10-fold more sensitive to the mutagenic effects of MTMC and 20-fold more sensitive to the mutagenic effects of MPMC than was strain NG30. NAC was not significantly mutagenic for NG30. The data suggest that the mutagenic effects of MTMC and MPMC are similar to that of N-methyl-N'-nitro-N-nitrosoguanidine, whereas that of NAC is similar to those of methyl methane-sulfonate or x-rays. The major damage to DNA by the three insecticides was not excisable by uvrA⁺-dependent excision repair and was probably methylation on the DNA. (7 refs)

79-0203 Reduced Carcinogenicity of Urethane for Thymusless Mice Compared with Their Immunologically Normal Siblings. (Rus) Kaledin, V. I. (Lab. Cancer Genetics, Inst. Cytology, Genetics, Novosibirsk, USSR); Gruntenko, E. V.; Morozkova, T. S. *Biull Eksp Biol Med* 86(11): 574-576; 1978.

The model of urethane carcinogenesis in athymic nude (nu/nu) mice was used for verification of Burnet's hypothesis on the role of immunological surveillance in oncogenesis. The progeny of the mating +/nu x +/nu (1/4 of which were nu/nu and 3/4 of which were phenotypically and immunologically normal) were inoculated ip with urethane (two 1-mg/g doses at a 7-day interval). The mice were paired (1 nude and 1 normal), and pairs were followed until the death of one of the partners, after which the second was sacrificed and the number of lung adenomas in the animals was compared. Of 10 immunologically normal mice, 7 were found to have lung adenomas, compared with 2/10 nude mice. The av number of adenomas per mouse was also significantly greater in normal mice than in their athymic siblings (1.2 and 0.2, respectively). (11 refs)

79-0204 Myelomatosis After Phenytoin Therapy. A Chance Association? (Eng) Matzner, Y. (Dept. Hematology, Hadassah Univ. Hosp., Jerusalem, Israel); Polliack, A. *Scand J Haematol* 21(4): 309-312; 1978.

The case report is presented of a 54-yr-old patient who developed monoclonal gammopathy followed by IgG-lambda

multiple myeloma during chronic (20-yr) diphenylhydantoin (phenytoin; Dilantin) therapy for epilepsy. The patient also suffered from diabetes mellitus and hypertension. He did not develop the signs of hypersensitivity to phenytoin or the lymphadenopathy during the 20 yr of continuous therapy prior to the development of the monoclonal gammopathy. The monoclonal gammopathy was found by chance, but within 8 mo classical multiple myeloma of IgG-lambda type had developed. Despite the known association between phenytoin and the development of immunosuppression and lymphoma, this case is regarded as a probable coincidence. Nevertheless, it is recommended that phenytoin-treated patients be examined regularly for lymphadenopathy and monoclonal gammopathy. (27 refs)

79-0205 Effect of 1,3-Bis(2-chloroethyl)-1-nitrosourea on *Escherichia coli* DNA Repair System. (Eng) Tashima, M. (First. Div. Internal Medicine, Faculty Medicine, Kyoto Univ., 53 Shogoin-Kawahara-cho, Sakyo-ku, Kyoto 606, Japan); Sawada, H.; Uchino, H.; Nishioka, H. *Gann* 69(5): 695-698; 1978.

The antibacterial effect of 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) on isogenic strains of *Escherichia coli* with normal or defective DNA repair systems was studied. Growth of strains lacking the *rec-A* gene was inhibited by BCNU at much lower concentration than in the case of those possessing it. This result suggests that BCNU-induced DNA damage in *E. coli* is effectively repaired by postreplication repair. (16 refs)

79-0206 Reaction of DNA with Alkylating Agents. Quantitation of Alkylation by Ethylnitrosourea of Oxygen and Nitrogen Sites on Poly[dA-dT] Including Phosphotriester Formation. (Eng) Jensen, D. E. (Fels Res. Inst., Temple Univ. Health Sciences Center, Philadelphia, PA, 19140); Reed, D. J. *Biochemistry* 17(24): 5098-5107; 1978.

The alkylation of oxygen and nitrogen sites on poly[dA-dT] by ethylnitrosourea (ENU) was studied by anion-exchange high-pressure liquid chromatography. The degree of phosphate group ethylation was 60% to 65% of the total assayed alkylation under a variety of reaction conditions. The phosphate reaction appeared to be independent of nucleotide base sequence. There was some reaction preference for one of the available oxygen sites in the phosphate group relative to the other, as determined by the resolution of ethyl dideoxynucleoside phosphotriester diastereomers. Some properties of these phosphotriester diastereomers are described. Quantitation of base alkylation showed a very high level of ethylation at the 2-position oxygen on the thymine moiety (approx 30% of the total alkylation). A low degree of ethylation occurred at the 4-position oxygen site on thymine and the 3-position nitrogen on adenine (3%-5% of the total ethylation pro-

ducts). Addition of sodium ion, tetramethylammonium ion, or magnesium ion to the poly[dA-dT]-ENU mixture resulted in a general decrease in total alkylation. The latter two ions decreased the base alkylation to phosphate alkylation ratio, whereas sodium ion had little effect. (37 refs)

79-0207 Reaction of DNA with Alkylating Agents. Differential Alkylation of Poly[dA-dT] by Methyl-nitrosourea and Ethylnitrosourea. (Eng) Jensen, D. E. (Fels Res. Inst., Temple Univ. Health Sciences Center, Philadelphia, PA, 19140). *Biochemistry* 17(24): 5108-5113; 1978.

The methylation of poly[dA-dT] resulting from incubation with methylnitrosourea (MNU) or ethylnitrosourea (ENU) was studied. Modification of the phosphate-group oxygen atoms using MNU accounted for 65%-75% of the total asayed alkylation under a variety of reaction conditions. Some reaction preference for one of the available nucleotide phosphate oxygen sites relative to the other was indicated, as determined by the differential yield of methyl dideoxynucleoside phosphotriester diastereomers. Methylation at the 3-position nitrogen atom on the adenine moiety amounted to approx 25% of the total alkylation. O²-thymine modification accounted for only 3%-5% of the total methylation products. MNU was approx twofold more effective than ENU with regard to total poly[dA-dT] alkylation. In contrast, ENU was much more effective at O²-thymidine alkylation, with this modification accounting for 40%-50% of the total methylation products. However, ENU alkylation of the 3-position nitrogen in deoxyadenosine was <10%. A reaction mechanism to account for these differences is discussed. (16 refs)

79-0208 Interaction of 1,1'-Ethylene-bis(1-nitrosourea) with Nucleic Acids and Proteins In Vitro. (Eng) Morimoto, K. (Dept. Medical Chemistry, Natl. Inst. Hygienic Sciences, Kamiyoga 1-18-1, Tokyo, Japan); Yamahara, T.; Miyahara, M.; Nakadate, M.; Suzuki, I. *Gann* 69(5): 649-655; 1978.

The binding of radioactivity from 1,1'-ethylenebis(1-nitrosourea) (EBNU) labeled with ¹⁴C in the carbonyl or ethylene residue to nucleic acids, proteins, and synthetic biopolymers was investigated in vitro. EBNU [carbonyl-¹⁴C] (9.5 μCi/mg) and EBNU [ethylene-¹⁴C] (8.1 μCi/mg) were incubated with a suspension of L1210 cells at 37 C, and binding of radioactivity was measured. The initial binding rate of both labeled compounds to the acid-insoluble fraction of the whole cells was the same for 30 min, after which the binding of radioactivity from EBNU [ethylene-¹⁴C] reached a max and that from EBNU [carbonyl-¹⁴C] continued to increase proportionally with time up to 3 hr. EBNU [carbonyl-¹⁴C] was bound to cytoplasmic and nuclear proteins but not to nucleic acids in L1210 cells, but that from EBNU [ethylene-¹⁴C] was bound to both proteins and nucleic acids. These findings were confirmed in model experiments in which puri-

fied nucleic acids, proteins, and synthetic biopolymers were used. The preferential binding of both labeled compounds to polylysine and polyhistidine as well as the selective binding of EBNU [ethylene-¹⁴C] to polyarginine might be responsible for the chemical and biological modification of basic proteins in chromatin by EBNU. (17 refs)

79-0209 Herbicidal Phenylalkylureas as Possible Mutagens: I. Mutagenicity Tests with Some Urea Herbicides. (Eng) Seiler, J. P. (Swiss Federal Res. Station, CH-8820 Waedenswil, Switzerland). *Mutat Res* 59(2/3): 353-359; 1978.

The mutagenic properties of 10 phenylalkylureas were tested in three different mutagenicity assays: (1) inhibition of testicular DNA synthesis (DSI), (2) the induction of point mutations in *Salmonella typhimurium* strain TA1535, and (3) chromosome damage assessed by the micronucleus test. Nine of the ten compounds gave positive results in the DSI test: N-methyl-N'-phenylurea, N,N-dimethyl-N'-phenylurea (fenuron), N,N-dimethyl-N'-(3-chlorophenyl)-urea, N,N-dimethyl-N'-(4-chlorophenyl)-urea monuron, N,N-dimethyl-N'-(3,4-dichlorophenyl)-urea (diuron), N,N-dimethyl-N'-(3-chloro-4-methylphenyl)-urea (chlorotoluron), N,N-dimethyl-N'-(3-chloro-4-methoxyphenyl)-urea (metoxuron), N,N-dimethyl-N'-(3-trifluoromethylphenyl)-methoxyphenyl)-urea (fluometuron), and N-methoxy-N-methyl-N'-(3,4-dichlorophenyl)-urea (linuron). Six of these nine compounds were weakly mutagenic in the *S. typhimurium* test. These compounds had a marginal effect on mammalian chromosomes, as evidenced by the very weak responses in the micronucleus test. The compound yielding negative results in all tests was N-methoxy-N-methyl-N'-(4-chlorophenyl)-urea (monolinuron). Since one member of this group of chemicals, monuron, is a recognized carcinogen, the results of the DSI assay indicate that a more thorough investigation of the mutagenic potential of these herbicides is needed. (16 refs)

79-0210 The Rate of Hydrolysis of Methyl Phosphotriesters in DNA under Conditions Used in Alkaline Sucrose Gradients. (Eng) Shooter, K. V. (Carcinogenesis Div. Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Bucks HP8 4SP, England); Merrifield, R. K. *Biochim Biophys Acta* 521(1): 155-159; 1978.

The relationship between the frequency of chain breaks in alkaline sucrose gradients and the concentration of phosphotriesters (PTE's) in DNA was investigated. Methyl PTE's were introduced into phage T7 DNA by incubating the latter with 0.08 mg/ml N-methyl-N-nitrosourea at 37 C for 30 min. The rate of PTE degradation in 0.3 M NaOH/0.7 M NaCl was determined by measuring the mean sedimentation rate of the DNA using boundary velocity ultracentrifugation. Hydrolysis of the methyl PTE's was complete after 15 hr at 20

C and after 2-3 hr at 37 C. The number of breaks/single strand of phage T7 DNA due to the PTE's alone was 11.7 at 20 C and 13.2 at 37 C, but continuous background degradation of DNA introduced an extra 3-4 breaks/molecule at 20 C and approx 6 breaks/molecule at 37 C. Therefore, the background rate was 6.3 and 63.0 breaks/10⁶ nucleotides/hr at the two temperatures, respectively. Incubation for 1 hr at 37 C would introduce breaks equivalent to the number produced by complete hydrolysis of the PTE's present and would probably lead to a best estimate of the concentration of these lesions. The background degradation rate would have to be considered in assessing the accuracy of the estimate. The nature of the alkyl group in the PTE may affect the hydrolysis rate in alkali and the fraction of the lesions that, on hydrolysis, lead to chain breaks rather than to simple loss of the alkyl group. - 79-0211 A New Animal Model for the Direct Induction of Neoplasms During Embryonic and Fetal Development.** (Eng) Jurgelski, W. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC); Hudson, P. M.; Dunn, R. L.; Falk, H. L. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 1033-1059; 1977.

Neoplasms induced postnatally with ethylnitrosourea (ENU) in the opossum were studied to demonstrate the potential of the opossum as a model for carcinogenesis. In two experiments, 532 opossums were divided by litter into 10 groups according to age (< 1 day, and 1, 2, 3, 4, 6, 8, 10, 12, and 16 wk). In the first experiment, animals were given approx 100 mg/kg ENU as a single po dose. In the second experiment, the same total dose was administered po in increments of 25 mg/kg given every other day. One or two animals in each litter served as controls. The animals developed a spectrum of mesenchymal and epithelial embryonal and 'adult type' neoplasms with diverse latencies and a range of malignancies comprising 43 different tumors distributed among 21 different sites. Several of the tumors previously had not been induced in laboratory species by systemic administration of a carcinogen. Fifty-four percent had one or more primary neoplasms; 73% of the tumor bearers had more than one primary. Thus, the opossum early in postnatal life is a useful model for the induction and characterization of certain of the major dysontogenetic neoplasms that have been difficult or impossible to reproduce in traditional laboratory species. The opossum also appears to have potential as a model for several tumors of adult life, particularly for malignant neoplasms of the lung, liver, intestine, and skin and, possibly, of the pancreas and prostate. It may be of special value in experimental perinatal carcinogenesis under conditions in which extrafetal activation or inactivation or a short biological half-life of the carcinogen may obscure or prevent the response of the target organ. - 79-0212 Notes on the Influence of N-Phenyl-N'-methylurea on Growth of B-77 Tumors in Rats.** (Slo) Paulov, S. (Univerzita Komenskeho, Bratislava, Czechoslovakia); Novotna, L. *Biologia* 33(8): 677-679; 1978.

The effect of N-phenyl-N'-methylurea (PMU; 0.025-2.500 µg/animal ip) on the growth of sc transplanted B-77 tumors (derived from LW embryonic fibroblasts transformed by B-77 avian sarcoma virus) was studied in six inbred Lewis LW rats weighing 180 g. PMU, administered 1 wk after tumor transplantation, markedly stimulated tumor growth, compared with that in two control animals not treated with PMU. The growth-stimulating effect was highest in the dose range 1-3 µg/animal, which caused a fivefold increase in tumor size, compared with the controls. A twofold increase in tumor size was induced by doses of 0.01-100 µg/animal. (5 refs)

- 79-0213 Changes in Surface Morphology Associated with Ethylnitrosourea-induced Malignant Transformation of Cultured Rat Brain Cells Studied by Scanning Electron Microscopy.** (Eng) Winslow, D. P. (Dept. Cell Pathology, Sch. Pathology Middlesex Hosp. Medical Sch., Riding House St., London W1P 7LD, England); Roscoe, J. P.; Rowles, P. M. *Br J Exp Pathol* 59: 530-539; 1978.

Cultures of cells clonally derived from either normal adult rat brain (ARBO) or a culture of a mixed glioma induced by ethylnitrosourea (ENU) were studied by scanning electron microscopy. ARBOC9 and ARBOC11 cultures, malignant glioma cultures A15A5 and A15A10, and rat brain cell clones (38D, 38E, 38F, 38G, 40D, and 40E) from rats transplacentally exposed to 40 mg/kg ENU were examined. Clones C9 and C11 were both extremely flat with few surface features; in particular, C11 cells were almost devoid of microvilli and had few intercellular filopodia. Cell boundaries were indistinct due to the very close contact between the cells. A15A5 and A15A10 clones, however, both consisted of extremely condensed bipolar cells, spherical cells, and pyramidal cells. Cell-cell and cell-surface contact was limited. Cell surfaces had long filopodia, some ruffles, and numerous blebs. The 38D, 38E, and 40D cultures were tumorigenic at the earliest times tested (30-33rd passage), and these cells appeared generally similar to A15A5 and A15A10 cell lines with many blebs, pleomorphic microvilli, and long filopodia, although these changes were less frequently seen in line 40D. The other brain cell cultures were not tumorigenic at the time of first testing and were composed mostly of flat cells with few surface features. Line 38F became tumorigenic at the 48th transfer, and at about this time it also began to demonstrate high surface activity. These results indicate that observed differences in cell surface activity represent a distinction between malignant and normal brain cells in culture. (20 refs)

- 79-0214 Toxicity of Ethylenethiourea in Pregnant Cats.** (Eng) Khera, K. S. (Bureau Chemical Safety, New Res. Center, Natl. Health and Welfare, Ottawa, Ontario, Canada K1A 0L2); Iverson, F. *Teratology* 18(3): 311-313; 1978.

To test the teratogenicity of ethylenethiourea (ETU) in cats, time-mated adult cats were given 5, 10, 30, or 60 mg/kg ETU po during days 16 to 35 of gestation or 120 mg/kg po from day 16 of gestation until signs of intoxication became evident (between days 27 and 34 of gestation). Cats given more than 5 mg/kg/day ETU showed toxicity of delayed onset characterized by wt loss, ataxia, tremors, and hind-limb paralysis. Four cats in the 30 mg/kg group, two in the 60 mg/kg group, and five in the 120 mg/kg group died or were killed in a moribund condition. Abortions occurred in all, including the untreated control groups and were unrelated to treatment. Nonpregnant cats were also found in all groups, the number being unrelated to treatment. Eleven of 35 live fetuses obtained from the moribund cats were malformed (coloboma, umbilical hernia, cleft palate, and/or spina bifida). Fetuses obtained from cats that remained healthy or outlived toxicosis showed no ETU-related effects on viability or wt. The data in general showed no clear evidence for teratogenicity of ETU in live fetuses. (7 refs)

- 79-0215 Determination of a Non-volatile N-Nitrosamine on a Food Matrix.** (Eng) Walters, C. L. (British Food Manufacturing Industries Res. Association, Randalls Rd., Leatherhead, Surrey, KT22 7RY, England); Downes, M. J.; Edwards, M. W.; Smith, P. L. *Analyst* 103(1232): 1127-1133; 1978.

A method devised for the determination of N-nitrososarcosine in soln, in which the N-nitrosamine in soln is denitrosated with hydrogen bromide to form volatile products that are rapidly removed and analyzed in a chemiluminescence analyzer, was extended to the determination of N-nitrososarcosine on a food matrix (powdered corn flakes). This procedure was carried out to determine whether the release of nitrogen oxide using hydrogen bromide is impaired in this situation. Nine 10-g samples of powdered corn flakes, each with 22 µg of added N-nitrososarcosine, were analyzed. The results obtained were in the range 15.4-19.3 µg, the mean value being 17.52 ± 1.53 µg. This method was less sensitive when used for N-nitrososarcosine determination in the food matrix than when used for determination in simple soln. Differentiation of N-nitrososarcosine and a number of other N-nitrosamines from inorganic nitrite was achieved by decomposing the nitrite with acetic acid prior to the denitrosation of the N-nitroso compounds. The other N-nitrosamines gave volatile products following denitrosation with hydrogen bromide that were detectable using a chemiluminescence analyzer; this was also true of the nitrosamides N-nitroso-N-methylurea, N-nitroso-N-ethylurea, and N-nitroso-N-methylurethane. Further, the procedure developed for the differentiation of N-nitrososarcosine and nitrite

was successfully extended to these N-nitrosamines and N-nitrosamides. The small amount of nitrosation of the secondary amines during the differentiation process was prevented by the addition of ascorbyl palmitate. In differentiating between large amounts of nitrite and much lower levels of N-nitroso-sarcosine on corn flakes, using a chemiluminescence analyzer, the duration of the response from the nitrite could be shortened by freeze-drying the food matrix in the presence of ascorbic acid. (13 refs)

- 79-0216 Analysis of Synthetic RNA-directed DNA Polymerase Activities in the Spleen of a Rat with Myelogenous Leukemia Induced by N-Nitroso-N-butylurea.** (Eng) Kozu, T. (Div. Serology and Virology, Saitama Cancer Center Res. Inst., Inamachi, Kitaadachi-gun, Saitama-ken 362, Japan); Aida, M.; Ikawa, Y.; Seno, T. *Eur J Cancer* 14(10): 1065-1076; 1978.

DNA polymerase activities from the spleen of a Sprague-Dawley rat with myelogenous leukemia induced by N-nitroso-N-butylurea were examined with respect to their possible association with RNA tumor viruses. Phosphocellulose chromatography of the extract from the leukemic spleen gave a single peak of poly(rA)-(dT)12-18-directed activity that coincided with that of DNA polymerase γ obtained from normal rat spleen, whereas chromatography of the extract from virus-producing cultured R35 rat mammary tumor cells or from the viruses themselves gave a unique peak of activity different from that of DNA polymerase γ . These viruses appeared to be one of the rat endogenous viruses similar to R35 virus. The peak from the leukemic spleen showed several enzymatic properties similar to those of DNA polymerase γ obtained from normal rat spleen, but different from those of the R35 viral DNA polymerase. The peak from the leukemic spleen responded to poly(rCm)-(dG)12-18, which is reported to be specific for viral reverse transcriptase. However, the DNA polymerase γ fraction from normal rat spleen also responded to the template primer to the same degree. Postmitochondrial fractions from the leukemic spleen gave poly(rA)-(dT)12-18-directed activity that sedimented at a density of 1.17 g/cm³ on sucrose. Addition of a nonionic detergent was not required for the activity. For the R35-like viruses, which banded at a density of 1.16 g/cm³, detergent was required to detect the activity. The results demonstrated that any unique DNA polymerase activity different from cellular DNA polymerase γ was not detectable from the spleen of a leukemic rat, under conditions in which reverse transcriptase activity was detectable in the virus-producing control rat cells. (33 refs)

- 79-0217 Mutagenicity of 4-Nitropyridine-1-oxide for *Salmonella typhimurium*.** (Eng) Auletta, A. E. (JRB Assoc., Inc., McLean, VA, 22101); Price, P. J. *Mutat Res* 58(2/3): 371-374; 1978.

4-Nitropyridine-1-oxide (4-NPO) was screened for mutagenic activity in *Salmonella typhimurium* and for its ability to

inhibit repair-deficient strains of this organism. Mutagenicity was determined using *S. typhimurium* strain TA100 in both a spot test and a pour-plate assay. Enzyme activation with liver microsomes was not performed because 4-NPO proved to be a direct-acting mutagen for *S. typhimurium*. In the repair test using strains TA1978 and TA1538 (repair deficient), there was no appreciable difference in the zone of inhibition of either strain with 4-NPO. In previous studies, 4-NPO had preferentially inhibited the growth of *polA*- strains of *Escherichia coli* over the parent wild-type strains but had no differential effect on cell killing between parent and UV-sensitive mutant strains of *B. subtilis* and *S. cerevisiae*. The UV-sensitive strains of *B. subtilis* and *S. cerevisiae* were also insensitive to methyl methanesulfonate and N-methyl-N'-nitro-N-nitrosoguanidine, suggesting a common factor in the repair mechanism for damage due to these agents and to 4-NPO. These results support the use of the Salmonella/microsomal assay as a prescreen for potential carcinogens. The results of the repair test suggest that the *polA*- mutants of *E. coli* are the organisms of choice for use in such an assay system. (8 refs)

79-0218 Survey of Cured Meat Products for Volatile N-Nitrosamines: Comparison of Two Analytical

Methods. (Eng) Havery, D. C. (Div. Chemistry and Physics, Food and Drug Admin., Washington, DC, 20204); Fazio, T.; Howard, J. W. *J Assoc Off Anal Chem* 61(6): 1374-1378; 1978.

Gas chromatography/mass spectrometry and mineral oil distillation-thermal energy analysis were used to analyze 106 cured meat samples for 14 volatile N-nitrosamines. N-Nitrosopyrrolidine (5-75 ppb) was confirmed in fried bacon, and unconfirmed trace levels of N-nitrosodimethylamine were found in other cured meats. There was good agreement between the analytical methods, especially at the 10-ppb level, and excellent agreement between analyses of an identical sample extract. (25 refs)

79-0219 The Oncogenic Implications of Chronobiotics in the Synchronization of Mammalian Circadian

Rhythms: Barbiturates and Methylated Xanthines. (Eng) Ehret, C. F. (Div. Biology and Medical Res., Argonne Natl. Lab., Argonne, IL, 60439); Dobra, K. W. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 1101-1114; 1977.

This study shows that levels of phenobarbital (PB) in the rat diet at and near those that are cocarcinogenic also induce circadian dyschronism. Male Charles-River rats fed 0.05%-0.3% PB in the diet for 7 days maintained nearly a

constant body temperature, whereas controls maintained a strong circadian rhythm of deep body temperature. Any tendency in the experimental animals toward circadian oscillation became less evident with increasing dosage. Power spectral analysis was used to determine if there was a decrease in the variance of the circadian component of the frequency spectrum and to determine if the transient frequencies were randomly distributed or if a dominant frequency with a < 24-hr period became evident. As the percent of PB in the diet increased, the variance of the 24-hr component diminished, and there was no significant increase in any other component of the frequency spectrum. Previous epidemiological evidence shows that persons at high risk of cancer include those who have had genetic deficiency diseases or who have taken drugs that interfere with the putative molecular-genetic pathways for circadian regulation, especially those interfering with the storage and regulation of energy reserves and the regulation of the catecholamine and indoleamine synthetic pathways. It is suggested that each time that the circadian biological oscillator in a cell is reset by a chronobiotic, there is increased risk of oncogenic damage to the gene-action machinery of the cell; for this reason, all chronobiotics may be oncogenic when taken at a vulnerable phase of the circadian cycle. (42 refs)

79-0220 Reproduction of Major Reactions of Aromatic Carcinogens with Guanosine, Using

HMO-based Polyelectronic Perturbation Theory. (Eng) Scribner, J. D. (Pacific Northwest Res. Foundation, 1102 Columbia St., Seattle, WA, 98104); Fisk, S. R. *Tetrahedron Lett* (48): 4759-4762; 1978.

Three different reactions with guanosine were correctly identified among five aromatic carcinogens, four aromatic amine derivatives and one polycyclic aromatic hydrocarbon derivative, using a simple calculation method. The method is based on the Huckel molecular orbital-based polyelectronic perturbation theory. According to this theory, the likelihood of a bond forming between an atom of a nucleophile and an atom of an electrophile depends on the perturbation energy that develops as these atoms approach each other. (9 refs)

79-0221 Chlorhexidine-induced Lingual Keratosis and Dysplasia in Rats. (Eng) Sonis, S. T. (Sidney

Farber Cancer Inst., Floor 17, Room 81, 44 Binney St., Boston, MA, 02115); Clark, W. B.; Shklar, G. *J Periodontol* 49(11): 585-591; 1978.

A study was undertaken to investigate the effect of chlorhexidine (CHD) ingestion on the tongue mucosa of Lewis rats. Forty-five animals were divided into six groups, the first of which comprised untreated controls (I). Other animals received 0.2% CHD in drinking water for 14 days before sacrifice (II); 0.2% CHD in drinking water for 14 days, then tap water before sacrifice at 30 days (IIa); 0.2% CHD in water for 14 days (III); 0.02% CHD in water for 30 days (IIIa);

and 0.2% CHD in water for 30 days (IV). All tongues were removed at sacrifice for histological examination. At 2 wk, approx 50% of the rats in groups II and IV and 20% of group III developed white plaques on the tongue, often associated with ulcerative changes and loss of papillae. Changes were most marked on the dorsal and lateral surfaces, but the ventral side was also affected. Microscopically, these plaques were identified as extensive keratosis, with accompanying dysplasia. Dysplasia was confirmed by hyperchromicity and enlargement of nuclei, with spindling and separation of cells. In regions of keratosis, the width of the stratum corneum was equal to the remainder of the stratified squamous epithelium, and connective tissue below the epithelium was chronically infiltrated with lymphocytes and histiocytes. These changes were present to a lesser degree in animals treated with 0.02% CHD. After one month, all rats in groups IIa, IIIa, and IV demonstrated varying degrees of a return to a normal state both grossly and microscopically, indicating that the animals had developed a tolerance to CHD toxicity. Further evaluation is needed of the progression and resolution of these pathological changes in response to CHD. (16 refs)

- 79-0222 Bromodeoxyuridine Mutagenesis in Mammalian Cells Is Stimulated by Thymidine and Suppressed by Deoxycytidine.** (Eng) Davidson, R. L. (Div. Human Genetics, Children's Hosp. Medical Center, Boston, MA, 02115); Kaufman, E. R. *Nature* 276(5689): 722-723; 1978.

The effects of deoxycytidine (CdR) and thymidine (TdR) on 5-bromodeoxyuridine (BUdR) mutagenesis were investigated in two pigmented Syrian hamster melanoma cell lines, RPMI 3460 and HAB-2E (derived from RPMI 3460, with all thymine residues in nuclear DNA replaced by bromouracil). In most studies, ouabain resistance (OB-r) was used as the marker for mutagenesis. The addition of 1 μ M CdR to the culture media decreased BUdR mutagenicity; a max decrease was obtained with 10 μ M CdR. Similar results were obtained in the presence of aminopterin, which blocks the conversion of CdR to TdR nucleotides, demonstrating that CdR suppresses BUdR mutagenicity without being converted to TdR nucleotides and without altering the amount of bromouracil in DNA. In the absence of CdR, BUdR mutagenicity occurred when the BUdR concentration exceeded 10 μ M. However, in the presence of CdR, BUdR mutagenicity did not occur until the BUdR concentration exceeded 30 μ M. The addition of 10 μ M TdR to 10 μ M BUdR increased the frequency of mutants while decreasing bromouracil substitution. The addition of 100 μ M TdR resulted in a similar stimulation of mutagenesis, even though the bromouracil substitution dropped to a very low level. Stimulation of mutagenesis by TdR was suppressed by CdR. The results were similar with both cell lines and with the use of OB-r or resistance to 18 μ M 6-thioguanine as a marker for mutagenesis. Interactions involving small molecules may play a central part in BUdR mutagenesis in mammalian cells. (15 refs)

- 79-0223 Synthesis of Mutagenic Principles Isolated from L-Glutamic Acid Pyrolysate.** (Eng) Take-da, K. (Faculty Pharmaceutical Sciences, Univ. Tokyo, Bunkyo-ku, Tokyo, Japan); Shudo, K.; Okamoto, T.; Kosuge, T. *Chem Pharm Bull (Tokyo)* 26(9): 2924-2925; 1978.

The synthesis of two mutagenic components of L-glutamic acid pyrolysate, 2-amino-6-methyldipyrido[1,2-a:3',2'-d]imidazole and 2-aminodipyrido[1,2-a:3',2'-d]imidazole, from 3-amino-8-methylimidazo[1,2-a]pyridine and 3-aminoimidazo[1,2-a]pyridine, respectively, is described. (7 refs)

- 79-0224 A Simple Plate Test for Screening Colicine-inducing Substances as a Tool for the Detection of Potential Carcinogens.** (Eng) Ben-Gurion, R. (Israel Inst. Biological Res., Ness-Ziona, Israel); *Mutat Res* 54(3): 289-295; 1978.

A simple and rapid plate test for screening substances that induce colicine E2 was studied. Colicinogenic auxotrophic bacteria, together with prototrophic indicator cells, were exposed to various test compounds on synthetic plates containing only small amounts of growth factors necessary for the growth of the tester bacteria. The inducing effect of the test compound could be measured quantitatively and was expressed in this way. All of the carcinogenic substances tested were positive in the induction plate test. A dose-response relationship was demonstrated for daunomycin, mitomycin C, and N-methyl-N'-nitro-N-nitrosoguanidine. Benzo(a)pyrene was inductive only after activation with S-9 mix. Chloramphenicol did not induce colicine, indicating that the test can distinguish between substances affecting DNA (presumably carcinogenic) and those affecting protein synthesis. The test is rapid and suitable for nonsterile material, and there are no complications due to phenocopies. (19 refs)

- 79-0225 Oncogenesis, Mutagenesis, DNA Damage, and Cytotoxicity in Cultured Mammalian Cells Treated with Alkylating Agents.** (Eng) Peterson, A. R. (Univ. Southern California Comprehensive Cancer Center, Cancer Res. Lab., Los Angeles, CA, 90033); Peterson, H.; Heidelberger, C. *Cancer Res* 39(1): 131-138; 1979.

Mutation to 8-azaguanine resistance in Chinese hamster V79 cells, and cytotoxicity and the production and repair of alkali-labile lesions in the DNA of V79 and transformable mouse embryo C3H/10T1/2 fibroblasts were measured after the cells had been treated for 2 hr with the monofunctional alkylating agents N-methyl- and N-ethyl-N'-nitro-N-nitrosoguanidine (MNNG and ENNG) and methyl and ethyl methanesulfonate (MMS and EMS). In both cell lines, methylating agents were more cytotoxic than equimolar concentrations of ethylating agents, and MNNG and ENNG were more cytotoxic than MMS and EMS. At equitoxic concentra-

tions, MNNG was 14 times as mutagenic as MMS and it produced 400 times as many alkali-labile lesions; ENNG and EMS produced similar numbers of alkali-labile lesions and were equally mutagenic. A plot of alkali-labile lesions vs mutations was a straight line, but the frequency of alkali-labile lesions was seven orders of magnitude greater than the frequency of mutations; the rate of repair of the alkali-labile lesions varied inversely as the first power of the number of lesions. These findings suggest that mutagenic and alkali-labile lesions are associated but not identical and that neither lesion is associated with cytotoxicity. The results are discussed in the light of chemical theories of alkylation and mutagenesis and are compared with previous studies that show that oncogenic and alkali-labile lesions are not uniformly associated. (33 refs)

- 79-0226 DNA Synthesis Inhibition in HeLa Cells as a Simple Test for Agents That Damage Human DNA.** (Eng) Painter, R. B. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143). *J Environ Pathol Toxicol* 2(1): 65-78; 1978.

Inhibition of HeLa cell DNA synthesis by DNA-damaging agents was investigated as a test for mutagenic carcinogens. Tests with 17 known carcinogens and/or mutagens showed a positive correlation between DNA synthesis inhibition and potential mutagenicity and/or carcinogenicity. The effect of two DNA-damaging agents administered simultaneously was examined. With UV light and N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), the effects were partly additive, but with MNNG and ICR-170 they were not. When UV light was administered simultaneously with hydroxyurea (HU), a non-DNA-damaging inhibitor of DNA synthesis, the UV effects were still evident after HU was removed and the HU-induced DNA synthesis inhibition was reversed. The inhibition of DNA synthesis by ICR-170 and by MNNG was less in xeroderma pigmentosum (XP) cells, which are deficient in excision repair, than in HeLa cells. Therefore, contrary to expectations, the use of a repair-deficient cell did not increase the sensitivity of the test. The sister chromatid exchange test for mutagens is more sensitive than the DNA synthesis inhibition test, but it takes longer and requires more specialized skills. Assays for unscheduled DNA synthesis are much less sensitive to intercalating agents, such as adriamycin, and to x-rays than are assays for inhibition of DNA synthesis. For routine screening procedures, it is suggested that the DNA synthesis inhibition assay be combined with the in vivo DNA synthesis inhibition test with mouse testes. (17 refs)

- 79-0227 Absence of Mutagenicity of Praziquantel, a New, Effective, Anti-schistosomal Drug, in Bacteria, Yeasts, Insects and Mammalian Cells.** (Eng) Bartsch, H. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, Lyon, France); Kuroki, T.; Malaveille, C.; Lo-

prieno, N.; Barale, R.; Abbondandolo, A.; Bonatti, S.; Rainaldi, G.; Vogel, E.; Davis, A. *Mutat Res* 58(2/3): 133-142; 1978.

The antischistosomal drug Praziquantel (PQ: 2-cyclohexyl-carbonyl-[1,3,4,6,7,11b]-hexahydro-2H-pyrazine [2,1-a] isoquinoline-4-one) was tested for its ability to produce genetic effects in various in vivo and in vitro short-term tests with and without metabolic activation. In the plate-incorporation assay with *Salmonella typhimurium* strains TA100 and TA98, reversion frequency was not increased with PQ concentrations up to 2 mM. At 5 mM, there was no increase in forward mutations in *Schizosaccharomyces pombe* at five adenine loci, and there were no mitotic gene conversions at the *ade2* or *trp5* loci in the D₁ strain of *Saccharomyces cerevisiae*. In a host-mediated assay utilizing male Swiss albino mice, 600 mg/kg did not increase forward mutation frequency in *S. pombe* or *S. cerevisiae* injected iv. At 5 mM, PQ induced no DNA lesions that led to DNA repair in human hetero-ploid cells, as measured by unscheduled incorporation of ³H-thymidine. In V79 Chinese hamster cells, 1 mM did not induce sister chromatid exchanges, toxicity, or 8-azaguanine- or ouabain-resistant mutants and 3 mM did not induce 6-thioguanine-resistant mutants. Finally, 1.25-5 mM PQ induced only 30 X-linked recessive mutations in *Drosophila melanogaster* out of 11,788 gametes tested, a rate equal to the spontaneous mutation frequency. These results prove that the antischistosomal effectiveness of PQ is not related to mutagenic activity. (37 refs)

- 79-0228 Deuterium Isotope Effects in Mutagenesis by Nitroso Compounds.** (Eng) Elespuru, R. K. (Frederick Cancer Res. Center, Cancer Biology Program, P.O. Box B, Frederick, MD, 21501). *Mutat Res* 54(3): 265-270; 1978.

The effects of deuterium on the ability of nitrosamines (which require activation by rat liver microsomes) and nitrosamides (which act directly) to induce reversion of a nonsense mutation in the *tyr* locus of *Escherichia coli* WU 3610 was studied. Both cyclic (nitrosomorpholine and dinitrosopiperazine) and open-chain (dimethylnitrosamine) nitrosamines containing deuterium induced only about half as many mutations as did unsubstituted compounds. In contrast, the deuterium-containing nitrosamides were indistinguishable from the unsubstituted analogs (N-methyl-N'-nitro-N-nitrosoguanidine and methylnitrosourea) in mutagenic effectiveness. Deuterium also did not affect the mutagenicities of the nitrosamides in *Haemophilus influenzae*. The results suggest that the metabolic activation of nitrosamines to a mutagenic species involves the loss of hydrogen, a reaction which the nitrosamides, in the absence of enzyme, do not undergo. (10 refs)

- 79-0229 Pancreatic Carcinogenesis and Naturally Occurring Pancreatic Neoplasms of Rats and Mice**

in the NCI Carcinogenesis Testing Program. (Eng) Milman, H. A. (Toxicology Branch, Carcinogenesis Testing Program, NCI, NIH, Bethesda, MD, 20014); Ward, J. M.; Chu, K. C. *J Environ Pathol and Toxicol* 1(6): 829-840; 1978.

The carcinogenicity of 2,4-dichloro-1-(4-nitrophenoxy)benzene (nitrofen: NF) and of azinphosmethyl (APM) to the pancreas in Osborne-Mendel (OM) rats is reported, and the rat and mouse as potential animal models for the study of pancreatic carcinogenesis were compared. Of > 200 chemicals examined in a bioassay system over a 2-yr period, only NF significantly increased the incidence of exocrine pancreatic adenocarcinomas (in female OM rats only), and only APM significantly increased the incidence of islet cell tumors (in OM rats only). The experiments involved administration (feeding, injection, or gavage) of the test chemicals at the max tolerated dose (MTD) and half the MTD to OM or Fischer 344 rats and B6C3F1 mice for 52-90 wk. After 78 wk of feeding NF in the diet to OM rats and B6C3F1 mice, a slightly significant increase in the incidence of exocrine pancreatic neoplasms was observed only in female OM rats (14% incidence with MTD). After 80 wk of feeding APM to OM rats and B6C3F1 mice, a significant increase in the combined incidence of islet cell adenoma or carcinoma was seen only in male rats receiving the MTD. These results suggest that the OM or Fischer 344 rat and B6C3F1 mouse may not be sensitive models for detecting chemically induced pancreatic neoplasms or that few pancreatic carcinogens were among the 200 chemicals tested. To test the latter hypothesis, the numbers of observations of neoplasms of the exocrine or endocrine pancreas were pooled by species, strain, and sex and compared with the pooled, observed incidence in controls. With the exception of adenocarcinoma of the pancreas of female OM rats, the major exocrine pancreatic neoplasms occurred primarily in male OM or Fischer 344 rats. However, the incidence was not significantly different from that seen in controls. Islet cell adenomas or carcinomas were significantly elevated in male Fischer 344 rats vs controls and treated female Fischer 344 rats, suggesting that male Fischer rats may be a suitable model for detecting chemically induced endocrine pancreas tumors. These tumors were also significantly elevated in treated male OM rats over their female counterparts but not over controls. The data suggest that male rats may be a sensitive model for endocrine but not exocrine pancreatic neoplasms. (18 refs)

79-0230 Chloroperoxidase-catalysed Oxidation of 4-Chloroaniline to 4-Chloronitrosobenzene. (Eng) Corbett, M. D. (Rosentiel Sch. Marine and Atmospheric Sci., Univ. Miami, 4600 Rickenbacker Causeway, Miami, FL, 33149); Chipko, B. R.; Baden, D. G. *Biochem J* 175(2): 353-360; 1978.

The chloroperoxidase (CPO)-catalyzed oxidation of 4-chloroaniline to 4-chloronitrosobenzene was studied. Incubation of the aniline with CPO and H₂O₂ resulted in the rapid formation of 4-chloronitrosobenzene. The optimum pH for the ini-

tial velocity of the reaction was 4.4, the catalytic center activity was 312/min, and the apparent K_m was 8.1 x 10⁻⁴ M for 4-chloroaniline. Both bromide and chloride anions accelerated the initial rate of the reaction, but they were not incorporated into the product. 4-Chlorophenylhydroxylamine was converted into the nitroso compound even more rapidly than was 4-chloroaniline. A reaction mechanism is proposed on the basis of the currently accepted theory for the catalytic action of CPO. The metabolism of anilines by CPO might serve as a model for the metabolic disposition of aniline pollutants in the marine environment. (38 refs)

79-0231 Mutagenicities of Styrene Oxide Derivatives on *Salmonella typhimurium* (TA 100). Relationship Between Mutagenic Potencies and Chemical Reactivity. (Eng) Sugiura, K. (Dept. Chemistry, Gakushuin Univ., Toshima-ku, Tokyo 171, Tokyo, Japan); Kimura, T.; Goto, M. *Mutat Res* 58(2/3): 159-165; 1978.

The lethal and mutagenic effects of *p*-methyl-, *m*-chloro-, *p*-chloro-, and unsubstituted styrene oxide (SO) on *Salmonella typhimurium* TA 100 were investigated. At equal concentrations, *p*-chloroSO was more lethal than *p*-methyl-, *m*-chloro- or unsubstituted SO. When the survival fraction was 0.8 or more, the mutagenicities of these compounds increased in the order: *m*-chloroSO oxide = *p*-chloroSO < SO < *p*-methyl-SO. The mutagenicities of these compounds depended only on the reactivity of their benzylic site; the reactivity at their primary site and their partition coefficients appeared to have no effect. (14 refs)

79-0232 Mutagenicity of Benzotrichloride and Related Compounds. (Eng) Yasuo, K. (Mitsubishi-Kasei Institute Toxicological, Environmental Science, 1000 Kamoshida, Midori-ku, Yokohama, Japan 227); Fujimoto, S.; Katoh, M.; Kikuchi, Y.; Kada, T. *Mutat Res* 58(2/3): 143-150; 1978.

Benzotrichloride (BTC), benzal chloride (BDC), benzyl chloride (BC), and benzoyl chloride (BOC) were tested for their mutagenicity in rec-assays using *Bacillus subtilis* and reversion assays using *Escherichia coli* WP2 and Ames *Salmonella typhimurium* TA strains, with or without metabolic activation in vitro. BTC and BDC required metabolic activation for their mutagenic activities in several strains of *E. coli* and *S. typhimurium*. Mutagenic BTC and BDC metabolites did not appear to be produced by hydrolysis. BC was weakly mutagenic without metabolic activation, but BOC exhibited no mutagenic activity in any assay. The mutagenic metabolite of BTC was unstable under the experimental conditions, but it was thought to be an intermediate between BTC and benzoic acid. *E. coli* WP2 *try hcr* was more sensitive than *E. coli* B/r WP2 *try (hcr +)* to the mutagenicity of BTC. (15 refs)

79-0233 Carcinogenic Activity of Aniline Dyes and Detection of Carcinogens in the Tissues. (Rus)

Korosteleva, T. A. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Skachkov, A. P.; Kondrat'eva, A. F. *Gig Tr Prof Zabol* (10): 22-26; 1978.

The carcinogenic activity of three dyes used in the textile industry was studied in random-bred rats and DBA mice. Rats were divided into two groups: group 1 was subjected to daily administration of fast violet C 100% dye (K1; 0.25-0.33 g/kg); group 2 received fast violet C 200% dye (K2; 0.25-0.33 g/kg). Mice were subjected to daily administration of fast black C 200% dye (K3; 0.4 g/kg). Dye K1 contained the benzidine group, and dyes K2 and K3 contained groups similar to 2-naphthylamine (2-NA). Some of the animals were sacrificed on days 4, 15, 30 and 60 after the initiation of the experiment, and the presence of benzidine and 2-NA haptens in various tissues was assessed by means of antisera against the heterologous antigens. The tissues of rats treated with K2 and mice treated with K3 did not contain benzidine or 2-NA, while rats treated with K1 contained antigen in the liver and kidneys (rats treated with dye for 30-60 days also had antigen in the sera and spleen). Of 47 rats who received K1 until natural death, only 18 survived 500 days of the experiment: 4/18 rats had nephrosclerosis, 4 had focal proliferation of the biliary ducts and precancerous diffuse hyperplasia of liver parenchyma and stroma, 2 developed leukemia, and 3 had renal cell carcinoma and plasmocytoma of the kidney. Of 43 rats treated with K2, 19 survived 500 days of the experiment: 2/19 rats developed acute liver dystrophy, and 1 had cirrhosis. (11 refs)

79-0234 Hairy-Cell Leukemia in a Subject Exposed to Benzene. (Fre)

Dally, S. (Clinique toxicologique, Hopital Fernand-Widal, 200, rue du Fg-St-Denis, 75475 Paris Cedex 10, France); Millet, B.; Gaultier, M. *Arch Mal Prof* 39(7/8): 487-488; 1978.

Hairy-cell leukemia was diagnosed in a man who was occupationally exposed to toluene, xylene, lead, titanium, and asbestos for 13 yr. Hairy cells accounted for 26% of the leukocytes at the time of diagnosis, and for 56% 6 mo later. It is impossible to ascertain a causal relationship between hairy-cell leukemia and exposure to benzene, because the patient was not exposed directly to this solvent, and it is impossible to establish retrospectively the benzene level in the toluene to which he was exposed. (no refs)

79-0235 Activity of Acid and Alkaline Phosphatase in Neutrophils of Rats Exposed to Benzene and Treated with Selenium. (Eng)

Moszczynski, P. (Provincial Immunological Lab., Kosciuszki St. 33, Pl-32-800 Brzesko, Poland); Starek, A.; Czarnobilski, Z.; Aleksandrowicz, J. *Folia Haematol (Leipz)* 105(4): 489-496; 1978.

The effects of two dosage levels of selenium on acid phosphatase (AcP) and alkaline phosphatase (AP) activity in peripheral blood neutrophils were evaluated in rats chronically exposed to benzene vapor. Male Wistar rats were given a single dose of 1.0 or 5.0 $\mu\text{g/kg}$ Se po 10 days before the start of benzene exposure (1,200 mg/cm^3 , 6 hr/day, 6 days/wk, for 12 wk). In animals exposed to benzene only, there was an increase in AcP and a decrease in AP in the neutrophils that correlated with exposure time and persisted for as long as 5 mo after exposure. Administration of 1.0 $\mu\text{g/kg}$ Se before benzene exposure prevented these enzymatic alterations. Administration of 5.0 $\mu\text{g/kg}$ Se, however, only prevented the decrease in AP activity and caused reactive neutrophilic leukocytosis. These results indicate the need for further studies of the effects of Se on immune reactions and its possible use in prophylaxis in persons professionally exposed to benzene and its homologs. (29 refs)

79-0236 A Case of Aplastic Anemia Presumably Related to Benzene Exposure Terminating in Acute

Myelogenous Leukemia with Myelofibrosis. (Jpn) Iwata, N. (Third Dept. Internal Medicine, Gunma Univ. Sch. Medicine, Maebashi, Gunma 371, Japan); Omine, M.; Tsuchiya, J.; Maekawa, T. *Jpn J Clin Hematol* 19(9): 1234-1240; 1978.

A 27-yr-old man who had been exposed to benzene for 8 yr was admitted with a diagnosis of aplastic anemia. He achieved hematologic remission 6 mo later following treatment with testosterone and oxymetholone. Three yr after resuming the occupational use of benzene, anemia and hemorrhagic diathesis recurred. On readmission, mild lymphadenopathy, but no hepatosplenomegaly, was noted. In addition to severe anemia and thrombocytopenia, a small number of myeloblasts and atypical monocytes were observed in the peripheral blood smear. Biopsy specimen of the bone marrow, which could not be aspirated, demonstrated a marked increase of fibrous tissue. A diagnosis of acute myelogenous leukemia (AML) with bone marrow fibrosis or acute myelofibrosis was suspected. Hepatosplenomegaly appeared gradually, and the atypical immature granulocytes increased in the peripheral blood, terminating in overt AML 1 yr after the second admission. Autopsy revealed hypercellular bone marrow infiltrated with leukemic cells. It is suggested that the prolonged exposure to benzene may play a causal role in the development of aplastic anemia and the subsequent transformation into AML associated with myelofibrosis. (14 refs)

79-0237 N,N-Diethyl-4-aminoazobenzene (DEAB): Acute Actions with Respect to Possible Carcinogenicity as Well as the Role of Solvents. Morphological and Pharmacological Investigations. (Eng)

Danz, M. (Pathologisches Institut der Friedrich-Schiller-Universitat, Ziegmuhlenweg 1, DDR-69 Jena, E. Germany); Klinger, W.; Muller, D.; Kleeberg, U.; Glockner, R.; Ziebarth, D.; Urban, H. *Exp Pathol (Jena)* 16(1-6): 245-253; 1978.

The acute effects of the noncarcinogenic azo dye N,N-diethyl-4-aminoazobenzene (DEAB) were investigated in male and female Sprague-Dawley (SD) and male Wistar (Wi) rats. The rats were given 50, 66, or 70 mg/kg DEAB dissolved in dimethyl sulfoxide (DMSO) or sunflower oil via stomach tube and sacrificed 48 hr later. In a separate experiment, the influence of various solvents on the excretion of DEAB and the potent hepatocarcinogen N,N-dimethyl-4-aminoazobenzene (DAB) was investigated in male Wi rats. DEAB was hepatotoxic to all rats receiving 66 or 70 mg/kg; it produced dose-dependent functional changes and slight structural alterations in the liver. The threshold dose for damage to hepatocytes was 50 mg/kg, as there was no liver cell death with this dose. The adrenocortical response to DEAB was dependent on solvent and rat strain. Adrenal mitoses were increased significantly in SD rats only when DEAB was dissolved in DMSO. Both solvents were effective in Wi rats, with the oil being more effective than DMSO. The cytochrome P-450-dependent N-demethylation of ethylmorphine and cytochrome P-448-dependent aryl hydrocarbon hydroxylation were inhibited by DEAB independently of the solvent used. In contrast, the hepatic N-demethylation of dimethylnitrosamine was reduced only by DEAB dissolved in oil. DMSO alone or with DEAB increased DMN N-demethylation 50% compared with oil-treated or untreated controls. The excretion of DEAB and DAB was delayed and the total amount excreted was reduced when the substances were dissolved in DMSO. The similarity of the results obtained with DEAB to those obtained with DAB and other carcinogens indicates that DEAB may also prove to be carcinogenic upon long-term testing. (31 refs)

79-0238 Promotion by Dietary Phenobarbital of Hepatocarcinogenesis by 2-Methyl-N,N-dimethyl-4-aminoazobenzene in the Rat. (Eng) Kitagawa, T. (Dept. Pathology Cancer Inst., Tokyo 170, Japan); Pitot, H. C.; Miller, E. C.; Miller, J. A. *Cancer Res* 39(1): 112-115; 1979.

The hepatocarcinogenicity of 2-methyl-N,N-dimethyl-4-aminoazobenzene, previously shown to be noncarcinogenic in adult rats in the absence of further treatment, was observed by following a 1- to 6-wk period of feeding this dye (0.06% of diet) to weanling male Donryu rats with the dietary administration of 0.5% phenobarbital up to 70 wk. Many large hepatocellular carcinomas developed in the phenobarbital-treated animals by 72 wk, whereas only a very small number of tiny neoplastic nodules, including one carcinoma, were seen in the rats not given this drug. This study suggests that the use of promoting agents, following the short-term administration of weak hepatocarcinogens, can be useful in demonstrating the initiating activity of such compounds. This system may be useful in identifying these agents in the environment. (21 refs)

79-0239 Enhancing Effect of Phenobarbital on the Development of Enzyme-Altered Islands and

Hepatocellular Carcinomas Initiated by 3'-Methyl-4-(dimethylamino)azobenzene or Diethylnitrosamine. (Eng) Kitagawa, T. (Dept. Pathology, Cancer Inst. Kami-Ikebukuro 1-37-1, Toshima-ku, Tokyo 170, Japan); Sugano, H. *Gann* 69(5): 679-687; 1978.

The effect of dietary phenobarbital (PB: 0.05%) on the development of enzyme-altered islands (EAI) and hepatocellular carcinomas initiated by short-term treatment with 3'-methyl-4-(dimethylamino)azobenzene (3'-Me-DAB) or diethylnitrosamine (DENA) was studied in male Donryu rats. PB generally enhanced the proliferation of carcinogen-induced EAI, so that the number and size of EAI were much larger in phenobarbital-fed groups by wk 12 than in control groups kept on a basal diet. The growth rate of EAI, however, was not uniform and only a small minority progressed to large islands or carcinomas. In rats fed a diet containing 0.06% 3'-Me-DAB for 3 wk, the enhancing effect of PB on cancer induction was remarkable by wk 36; but in rats fed 0.06% 3'-Me-DAB for 1 wk, no cancer developed by wk 60, although a large number of small EAI appeared. Thus, a summation effect of the carcinogen was observed even when it was given for a short period as an initiator. The enhancing effect of PB was also marked in rats initiated by DENA (2 mg ip); however, a considerable number of carcinomas also developed in control rats given ip DENA + a basal diet. Most of the DENA-initiated tumors were trabecular carcinomas, but approx 40% of the 3'-Me-DAB-initiated tumors were adenocarcinomas. The carcinogen-induced and EAI populations differed in that the DENA induced cells showed a greater potential to progress to carcinomas. (23 refs)

79-0240 Changes in Toxicity and Carcinogenicity of N-Methyl-N-Nitrosobenzylamine in Rats by Methyl Substitution on the C-Atoms Adjacent to the Nitrogen. (Ger) Schweinsberg, F. (Hygiene-Institut der Universität, Silberstrasse 7, D-7400 Tübingen, W. Germany); Kouros, M.; Manncke, K.; Rieth, K. *Z Krebsforsch* 92(3): 235-241; 1978.

The effect of methyl-substitution on the C-atom alpha to the N atom on the carcinogenicity and toxicity of N-nitroso-N-methyl-benzylamine (NMBA) in SIV 50 female rats was studied. NMBA selectively produces tumors in the esophagus and pharynx of rats; oxidation of the proton on the alpha C-atom is thought to be the first step in formation of the ultimate carcinogen. In the acute toxicity studies, the compound was given in one dose in edible oil by stomach tube. These rats (av wt, 200 g at dosage time) were weighed daily for 2 wk. For the long-term studies, rats with an av starting wt of 120 g were given one compound in their drinking water at 10, 15, or 30 ppm. The previously published LD₅₀ for NMBA is 18 mg/kg. For N-nitroso-N-methyl-(1-phenyl)-ethylamine (NMPE) the LD₅₀ was 600 mg/kg; for the N-nitroso-N-methyl-2-(2-phenyl)-propylamine derivative (NMPP), the LD₅₀ was 2,100 mg/kg; for N-nitroso-N-ethyl-benzylamine (NEB), the LD₅₀ was 250 mg/kg. None of the

rats given NMPP showed any sign of the cancerous changes associated with NMBA. They were observed for 23 mo. Rats given NEB at 30 ppm began to show symptoms (wt loss, respiratory difficulty) at 4.5 mo. Those given NMPE at 30 ppm showed similar symptoms at 8.5 mo. The rats given NEB or NMPE were observed until death. All of them had precancerous or cancerous changes of the esophagus. The lesions resembled keratinizing squamous cell papillomas with partial malignant degeneration. Thus NMPE possesses carcinogenicity with the same distribution of sites as given by NMBA; symptoms appeared later with NMPE. Steric hindrance of enzymatic attack on the H atom remaining on the alpha-C can explain this result. The ultimate carcinogen cannot be formed from NMPP because no proton remains on the alpha-C; thus NMPP is no longer carcinogenic under the selected conditions and has a low acute toxicity. Oxidation of a proton on the alpha-C can occur in NEB, and this compound is carcinogenic, as expected. Different effects of substituents on the carcinogenicity and acute toxicity of a compound may result from the many different mechanisms by which a compound may be toxic. (8 refs)

79-0241 Histopathology of the Rat Liver Following a Single Autoprotective Dose of 3'-Methyl-4-dimethylaminoazobenzene. (Eng) Flaks, A. (Cancer Res. Unit, Dept. Biology, Univ. York, Heslington, York YO15DD, England); Flaks, B. *J Pathol* 126(2): 71-78; 1978.

The possible carcinogenic or other persistent effects of a single 1.2 g/kg po dose of 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB) were investigated in 95 Leeds rats. Two rats were killed and examined histologically at 24, 48, and 72 hr, and 3, 5, and 7 days after treatment, after which three rats were killed at weekly intervals up to 42 days, and the remaining rats were killed in groups at 3, 4, 8, 12, and 14 mo after treatment. Glycogen depletion was evident in centrilobular zones at 24 hr, and whole lobes were involved at 48 hr. There was no significant recovery in glycogen stores until 21 days, and for the duration of the experiment most hepatocytes were lacking normal glycogen stores. Hepatocellular necrosis was evident at 3 days, but resolved by 7 days. Hepatocytes that did not become necrotic were of variable size, some containing giant nuclei and displaying a mild degree of regenerative hyperplasia; normal morphology was usually not recovered over the duration of the experiment. Oval cells with large pale nuclei appeared at 3 days; they proliferated to involve whole lobules and distorted liver architecture at 14 days, but largely disappeared by 35 days. Hepatic parenchymal cells contained numerous small lipid and hyaline inclusions up to 7 days. From 4 mo onward, there was a progressive increase in the abundance of "clear cells". Although no tumors were found in these animals, it appears that a single dose of 3'-MeDAB can induce histopathological changes in rat livers similar to those seen in carcinogenesis, while avoiding severe toxic damage and permitting long-term survival in most animals. (27 refs)

79-0242 Cytogenetic Effects of Styrene and Styrene Oxide. (Eng) Linnainmaa, K. (Dept. Industrial Hygiene, Toxicology, Inst. Occupational Health, Helsinki, Finland); Meretoja, T.; Sorsa, M.; Vainio, H. *Mutat Res* 58(2/3): 277-286; 1978.

The cytogenetic effects of styrene (S) and styrene oxide (SO) were compared in human lymphocyte cultures and root-tip cells of the onion *Allium cepa*, caused chromosome breaks in both test systems, and in *Allium* it had a strong c-mitotic effect. SO, on the other hand, appeared to destroy the tertiary folding of chromatin. The cytotoxicity of SO was very high (complete mitotic inhibition occurred at 0.03% volume solute/volume solvent) in human lymphocytes, but S was slightly more toxic than SO in *Allium*. Styrene glycol, another SO metabolite did not cause mitotic inhibition. (15 refs)

79-0243 The Expression Curve of Mutants Induced by Styrene Oxide at the HGPRT Locus in V79 Cells. (Eng) Bonatti, S. (Laboratorio di Mutagenesi e Differenziamento del CNR, Pisa, Italy); Abbondandolo, A.; Corti, G.; Fiorio, R.; Mazzaccaro, A. *Mutat Res* 52(2): 295-300; 1978.

The decrease in the frequency of 8-azaguanine (AG)- and 6-thioguanine (6TG)-resistant clones induced by styrene oxide (SO) in V79 Chinese hamster cells after a max had been reached was investigated. Twenty-seven AG- or 6TG-resistant clones were isolated at 90 hr (Group 1) or 210 hr (Group 2). All isolates showed cross-resistance and maintained the resistant phenotype during subsequent cultivation in the absence of either selective drug. The spontaneous reversion frequency on HAT medium was $\leq 10^{-6}$ for seven Group 1 and seven Group 2 clones. In a group of 18 mutants induced by ethyl methanesulfonate (EMS), 9 reverted with comparable low frequency. Thus, the resistant phenotype of clones appearing at the time of max expression (90 hr) is not unstable. The cloning efficiency of Group 1 mutants was poor: for 7/13 mutants, the colony forming ability was $< 50\%$. The same was true for only two Group 2 mutants, a statistically significant difference. Moreover, the growth curves of four Group 1 isolates showed that they all grew at a lower rate than that of the parental cells. Thus, the SO-induced resistant clones were likely outgrown by wild-type cells during cultivation in unselective medium. The reason for the low division rate in SO-induced mutants is not known. In addition, 11/24 Group 1 and 2 clones analyzed showed $> 5\%$ polyploid cells vs only 1 clone among 18 EMS-induced mutants. It is not known whether the incidence of polyploid cells was causally related to the decline of the expression curve. (5 refs)

79-0244 Mutagenicities of Phenacetin and Its Metabolites. (Eng) Shudo, K. (Faculty Pharmaceutical Science, Univ. Tokyo, 7-3-1, Hongo, Bunkyo-ku, Tokyo 113,

Japan); Ohta, T.; Orihara, Y.; Okamoto, T.; Nagao, M.; Takahashi, Y.; Sugimura, T. *Mutat Res* 58(2/3): 367-370; 1978.

The mutagenicity of phenacetin and its metabolites was tested in *Salmonella typhimurium* strains TA100 and TA98 with and without microsomal activation. Phenacetin itself exerted no mutagenicity on either strain with or without activation. N-Hydroxyphenacetin (N-OH-Ph) with microsomal activation was mutagenic to TA100 but not to TA98; it was not mutagenic to either strain without activation. N-Acetoxyphenacetin (N-OAc-Ph) was mutagenic to both TA100 and TA98 with activation but to neither strain without activation. N-Acetylbenzoquinone imine had no mutagenic activity on either strain, with or without microsomal activation. These results indicate that N-OAc-Ph is a more proximate mutagen than is N-OH-Ph, since it is mutagenic to TA98, which is not susceptible to N-OH-Ph. However, N-OAc-Ph is not an ultimate mutagenic form since it still required metabolic activation. (16 refs)

79-0245 Fluoroxene Mutagenicity. (Eng) Baden, J. M. (Dept. Anesthesia, Stanford Univ. Sch. Medicine, Stanford, CA); Kelley, M.; Simmon, V. F.; Rice, S. A.; Mazze, R. I. *Mutat Res* 58(2/3): 183-191; 1978.

The volatile anesthetic fluroxene (FL) (2,2,2-trifluoroethyl vinyl ether), which contains the stabilizer N-phenyl-1-naphthylamine, was tested for mutagenicity in *Salmonella typhimurium* strains, TA1535, TA1537, TA98 and TA100, and *Escherichia coli* strain, WP2. In addition, purified FL; N-phenyl-1-naphthylamine; trifluoroethanol (a major FL metabolite), and urine from rats anesthetized with FL were tested. Several procedures were used, including exposure of bacteria to vapor in desiccators and in liquid suspension. FL, but not its stabilizer, was mutagenic to strains TA1535, TA100, and WP2 only in liquid suspension and only in the presence of a rat-liver enzyme system. Trifluoroethanol and urine from FL-treated rats were not mutagenic to any strain of bacteria. These findings indicate that FL is a promutagen that requires preincubation before it is recognized. Further experiments were performed with enzymes prepared from mouse, hamster and human liver. FL was mutagenic only in the presence of enzymes from Aroclor 1254-pretreated rodents. Since FL was not mutagenic in the presence of enzymes from three human livers, the significance of these findings for humans are unclear. However, the possibility that FL has contributed to the increased incidence of malignancies in operating personnel cannot be excluded. (17 refs)

79-0246 Phenyl-beta-naphthylamine. (Eng) Garfinkel, L. (Dept. Epidemiology and Statistics, American Cancer Society, New York, NY). *CA* 28(2): 116; 1978.

The higher risk of bladder cancer and leukemia in rubber

industry workers cannot be attributed to phenyl- β -naphthylamine, as these workers are exposed to several other chemicals, notably benzene. (no refs)

79-0247 Carcinoma of the Larynx in Naphthalene Distillation Workers. (Ger) Wolf, O. (Hals-Nasen-Ohren-Klinik, Bezirkskrankenhaus Dessau, Auenweg 38, DDR-4502 Dessau-Alten, E. Germany). *Z Gesamte Hyg* 24(10): 737-739; 1978.

Four of 15 male naphthalene distillation workers from one chemical plant developed laryngeal carcinoma, an abnormal incidence compared with that in the general male population in East Germany (6.3/100,000). The workers had been exposed to naphthalene sublimate and tar vapors. The length of the occupational exposure was 7-31 yr, the latent period 13-32 yr. All four patients were smokers. Solid immature squamous cell carcinoma, pleomorphic undifferentiated carcinoma, and keratinizing and nonkeratinizing squamous cell carcinomas were found. The findings indicate the occupational hazards of exposure to naphthalene and tars. (9 refs)

79-0248 Photodegradation of 3,3'-Dichlorobenzidine. (Eng) Banerjee, S. (Life Sciences Div., Syracuse Res. Corp., Merrill Lane, University Heights, Syracuse, NY, 13210); Sikka, H. C.; Gray, R.; Kelly, C. M. *Environ Sci Technol* 12(13): 1425-1427; 1978.

The photodegradation of 3,3'-dichlorobenzidine (DCB) and 3-chlorobenzidine was studied. Irradiation of aqueous solutions of DCB resulted in sequential degradation to monochlorobenzidine (MCB) and benzidine and to the formation of more than five relatively water-insoluble products that appeared to be dimers or higher analogues of DCB and/or its photoproducts. Irradiation of DCB in noonday sunlight confirmed the expected photolability of DCB. Disappearance quantum yields for DCB and MCB were high, whereas that for benzidine was much lower. Virtually no degradation occurred following irradiation of DCB in hexane, 2-propanol, or methanol. The photoreduction of DCB appears to involve a mechanism different from simple homolysis of the carbon-chlorine bond. Proton transfer appears to be involved and the dechlorination process may proceed through an ionic pathway involving the loss of chloronium ion from the excited DCB molecule. (15 refs)

79-0249 Modified Method for Determination of Urinary Benzidine. (Eng) Dangwal, S. K. (Central Labor Inst., Sion, Bombay 400 022, India); Kadam, V. T.; Jethani, B. M. *Am Ind Hyg Assoc J* 39(12): 1019-1022; 1978.

An analytical method for the determination of urinary benzidine is presented. The method is based on the colorimetric

estimation of the yellow merquinodal complex formed by the reaction of solvent-extracted benzidine with chloramine T. If samples were preserved and adjusted to pH 7.5 with HCl, precipitate formation was prevented, and the av percentage recovery of benzidine was 80%. (5 refs)

- 79-0250 Effects of Carcinogenic and Noncarcinogenic Chemicals on Nuclear DNA Synthesis Rate and Labeling Index in Growing CBA Mice. The Thymidine-Incorporation Screening System (TSS).** (Ger) Amlacher, E. (Pathologisches Institut, Friedrich-Schiller-Universität, Ziegmühlweg 1, DDR-69 Jena, E. Germany); Rudolph, C. *Exp Pathol (Jena)* 16(1-6): 69-82; 1978.

The effects of single doses of 21 carcinogenic and 9 noncarcinogenic chemicals on nuclear DNA synthesis in the renal tubular and liver epithelial cells of CBA mice were studied by a thymidine-incorporation screening system (TSS) using autoradiography. The animals were inoculated with ^3H -thymidine (3 $\mu\text{Ci/g}$ ip) 24 hr after they were administered the chemicals and killed 50 min later. Twenty of the 21 carcinogens had a significant suppressive effect on nuclear DNA synthesis; the carcinogen 1-aminophthaline and all the noncarcinogens had no such effect. Actinomycin D, a suspect carcinogen, caused a significant increase in thymidine incorporation. Among the carcinogens, nitrosamines and nitrosamides were especially active in terms of suppression of nuclear DNA synthesis. The thymidine labeling index failed to show any systematic differences between carcinogens and noncarcinogens. The findings indicate the usefulness of TSS in screening for chemical carcinogens. (46 refs)

- 79-0251 The Mutagenic Effect of Benzene, Toluene and Xylene Studied by the SCE Technique.** (Eng) Gerner-Smidt, P. (Inst. Human Genetics, Univ. Aarhus, DK-8000 Aarhus C, Denmark); Friedrich, U. *Mutat Res* 58(2/3): 313-316; 1978.

The effects of benzene, toluene, and xylene on human lymphocytes were examined in vitro with respect to changes in the rates of occurrence of sister-chromatid exchanges (SCE), structural chromosomal aberrations, and cell growth. Three concentrations of the solvents were tested: 1.52 mg/ml, 15.2 $\mu\text{l/ml}$ and 152 $\mu\text{g/ml}$. None of the chemicals tested changed the number of SCE or the number of chromosomal aberrations in the lymphocytes. The two highest concentrations of toluene and the highest concentration of xylene showed positive results in the growth inhibition test. Since benzene and toluene are known to induce chromosomal aberrations in humans and in animals, these results suggest that it is the metabolites of these compounds that are mutagenic and not the organic solvents themselves. (13 refs)

- 79-0252 Characterization of Carbon Black Adsorbates and Artifacts During Extraction.** (Eng) Fitch, W. L. (Acurex Corp., 485 Clyde Ave., Mountain View, CA, 94042); Everhart, E. T.; Smith, D. H. *Anal Chem* 50(14): 2122-2126; 1978.

Materials obtained by extraction of three commercial carbon black samples (lampblack, 2 channel black samples) with benzene and naphthalene (NT) were identified by combined gas chromatography/mass spectrometry and advanced computer techniques. Extraction of the channel blacks with benzene alone yielded oxidized polynuclear aromatic hydrocarbon (PAH) derivatives in ppm quantities, including ketones, quinones, anhydrides, and nitro compounds. When benzene/methanol mixtures were used for Soxhlet extraction of the channel blacks, PAH polycarboxylic acid methyl esters were obtained, presumably by acid-catalyzed esterification on the highly acidic surface of the black. When these carbon samples were extracted with NT, using a special apparatus designed to maintain the solvent in liquid form at elevated temperature and reduced pressure, the major extractable materials were different from those seen in the benzene extracts. They include three binaphthyls, 2 dinaphthofurans, and 2 methylbinaphthyls, believed to be formed by reaction of NT with surface groups of the carbon. A control experiment confirmed that these binaphthyls and derivatives were not adsorbed species on the channel blacks. Similar extractions of lampblack yielded PAH, but only traces of the oxidized species and none of the NT artifacts. NT was more efficient at extracting high-mol-wt PAH than benzene; the lower mol-wt PHA were partially lost during NT distillation. (30 refs)

- 79-0253 Comparative Studies of the Carcinogenic Polycyclic Aromatic Hydrocarbons in the Environment.** (Hun) Kertesz, M. (Országos Kozegészségügyi Intézet, Budapest, Hungary); Horvath, A.; Kiss, A.; Morlin, Z.; Toth, B.; Heszina, A. Ja.; Smirnov, G. A.; Shabad, L. M. *Egészségtudomány* 22(3): 245-252; 1978.

Polycyclic aromatic hydrocarbon concentrations in the air and soil were measured in different areas in Hungary. The concentrations were highest in center city Budapest and lowest in suburban and recreational areas. Phenanthrene, fluoranthene, pyrene, chrysene, benz(a)anthracene, benz(b)fluoranthene, perylene, benzo(e)pyrene, benz(a)pyrene, benzo(ghi)perylene, benzo(rst)pentaphene, dibenz(a,i)anthracene, dibenz(a,h)anthracene, and coronene were found. (12 refs)

- 79-0254 The Effect of Some Cigarette Smoke Constituents and Other Compounds on the Metabolism of Benzo(a)pyrene in Rabbit Lung 9000g Supernatant.** (Eng) Hulshoff, A. (Farmaceutisch Laboratorium van de Rijksuniversiteit, Catharijnesingel 60, Utrecht, The Netherlands);

Lubawy, W. C.; Kostenbauder, H. B. *Xenobiotica* 8(11): 711-717; 1978.

The inhibitory effects of a number of compounds, some of which occur in cigarette smoke, on benzo(a)pyrene (BP)-metabolizing enzymes were studied in lung homogenates (9,000 x gravity supernatant) of 3-methylcholanthrene (MC)-treated and control rabbits. BP (0.8 nmol) was incubated with the homogenate and various concentrations of each inhibitor for 15 min. BP and its metabolites were determined by liquid scintillation counting. MC treatment caused a six-fold increase in metabolic activity compared with homogenates from untreated rabbits. Of the cigarette smoke constituents tested, naphthalene, naphthol, and anthracene were the most potent inhibitors of the BP-metabolizing enzymes. Nicotine and phenol were somewhat less active in this respect. The results suggest that, in the case of some of the structurally related compounds, the more lipophilic ones are also the more active inhibitors. The inhibitors could be divided into two groups on the basis of mode of action: (1) those inhibiting primarily benzo(a)pyrene hydroxylase activity (phenol, 1-naphthol, nicotine, and acetone) and (2) those inhibiting the activity of both the epoxide-metabolizing enzymes and BP hydroxylase (naphthalene, anthracene, and chlorpromazine). The most active inhibitors (anthracene, naphthol, and chlorpromazine) also caused a significant decrease in the amount of BP bound covalently to tissue macromolecules. These results indicate that the data obtained with the frequently used fluorescence technique for determining BP-hydroxylase activity, can be misleading when used for determining changes in BP metabolism with certain inhibitors. (33 refs)

79-0255 Hansch Analysis, Free Wilson Analysis, and Sub-structure Analysis. (Eng) Craig, P. N. (Franklin Inst., Philadelphia, PA, 19103). In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 63-67; 1978.

The purpose of structural correlation analysis is to develop a mathematical relationship between chemical structure (or physical properties) and biological effect in order to predict the activities of untested compounds. The Hansch approach assumes that one or at most a few parameters are of importance. Through multiple regression analysis computer programs, an attempt is made to correlate all possible combinations of these parameters with the desired biological response. Regression analyses of a series of structurally related compounds may give a linear relationship between a parameter and biological activity or equations involving parabolic terms or steric constants. The basic assumption of the Free-Wilson method is that each time a substituent group appears in the same substituent group position, it makes a constant contri-

bution to the overall biological activity of the molecule; the only variables are the activity and the chemical structure. Results of analyses of the same series of antimalarial phenanthrenes revealed that the Hansch and Free-Wilson methods paralleled each other. Although modification is necessary for application of these methods estimating the carcinogenicity and mutagenicity of compounds, the methods show promise for this purpose. (7 refs)

79-0256 Methylbenz(a)anthracenes: Correlations Between Theoretical Reactivity Indices and Carcinogenicity. (Eng) Smith, I. A. (Dept. Chemistry, Wright State Univ., Dayton, OH, 45435); Seybold, P. G. *Int J Quant Chem Quant Biol Symp* (5): 311-320; 1978.

The presumed in vivo metabolic transformations of methylbenz(a)anthracene (MBA) compounds were examined using orbital reactivity indices, in order to explain the differences in the carcinogenic activity (CA) of the MBA's. These studies suggested that methyl substitution on the benzo ring of BA (carbons 1, 2, 3, and 4) leads to inactive derivatives, because these methyl groups hinder a reaction crucial to CA. Analogous substitutions may decrease or eliminate CA in other polycyclic aromatic hydrocarbons. When methyl substitution increases the reactivity of the B-region bond of the dihydrodiol form or increases the stability of the resulting "bay region" carbonium ion, CA is enhanced. The latter seems to be an especially accurate guide to CA. These results and those of previous studies strongly suggest that reactions leading ultimately to "bay region" carbonium ions form an important pathway for CA in these compounds. The carcinogenic reactions were susceptible to reasonably accurate analysis using reactivity indices taken from molecular orbital theory. By implication, electronic factors appear to be critical in determining the CA of polycyclic aromatic hydrocarbons, rather than enzyme specificities, solubilities, diffusion rates, or other factors that, a priori, might be expected to play strong roles. (34 refs)

79-0257 Reactions of the Carcinogens 7-Hydroxymethyl-12-methylbenz(a)anthracene and 7-Acetoxy-methyl-12-methylbenz(a)anthracene with DNA. (Eng) Flesher, J. W. (Dept. Pharmacology, Univ. Kentucky Coll. Medicine, Lexington, KY, 40506); Tay, L. K. *Res Commun Chem Pathol Pharmacol* 22(2): 345-355; 1978.

The covalent reactions of the carcinogens 7-hydroxymethyl-12-methylbenz(a)anthracene (7-HOMe-12-Me-BA) and 7-acetoxymethyl-12-methylbenz(a)anthracene (7-AcOMe-12-Me-BA) with calf thymus DNA were studied. 7-HOMe-12-Me-BA reacted poorly with DNA [2 micromoles (μ mol) hydrocarbon/mole DNA P] in the absence of enzymes, whereas 7-AcOMe-12-Me-BA reacted readily (21.4 μ mol hydrocarbon/mole DNA P). In the absence of

a PAPS generating system and ATP, 7-HOMe-12-Me-BA did not react with DNA, but in the presence of the complete system, considerable reaction occurred (27.2 μ mol hydrocarbon/mole DNA P). If sulfate ion was omitted from the reaction mixture, 22.4 μ mol hydrocarbon/mole DNA P was generated, whereas if ATP was omitted, only 0.4 μ mol/mole DNA P was obtained. If enzyme was omitted, the reaction occurred in the presence (44.8 μ mol/mole DNA P) but not in the absence of ATP. ADP was also active, although less so, whereas AMP and adenosine were inactive. The data demonstrate that ATP mediates the nonenzymatic reaction of 7-HOMe-12-Me-BA with DNA, suggesting the formation of a reactive phosphate ester. (18 refs)

79-0258 Modulation of Rat Guanylate Cyclase Activity In Vitro by Chemical Carcinogens. (Eng) Vesely, D. L. (Div. Endocrinology and Metabolism, Dept. Medicine, Univ. Miami Sch. Medicine, P.O. Box 875, Miami, FL, 33152); Lehotay, D. C.; Levey, G. S. *Enzyme* 23(5): 356-360; 1978.

Compounds from several major classes of carcinogens were examined for their effects on guanylate cyclase (GC) activity and cyclic guanosine 3',5'-monophosphate (GMP) levels in male Sprague-Dawley rat liver slices. Compounds tested were chloromethyl methyl ether (α -halo ethers), benzidine and B-naphthylamine (aromatic amines), methyl yellow (azo dyes), 1,2-benzanthracene and acridine (polycyclic hydrocarbons), aflatoxin B₁, B₂, G₁, and G₂, and N'-nitro-N-nitroso-N-propylguanidine (NNPG, nitrosamines). All of the compounds except NNPG significantly decreased GC activity in liver preparations in vitro at a concentration range of 0.5-13 millimoles (mmol)/liter. In these same preparations, NNPG (1 mmol/liter) produced a 20-fold stimulation of GC activity. None of the carcinogens had significant effects on renal or hepatic adenylate cyclase. NNPG and butadiene diepoxide (another stimulator of GC) increased cyclic GMP levels in liver slices by five- and fourfold, respectively, while benzidine and chloromethyl methyl ether decreased cyclic GMP levels by 30% and 71%, respectively. Some of the nitrosamides that increase GC activity also increase DNA synthesis, but carcinogens that decrease GC activity inhibit DNA or RNA synthesis, which suggests a relationship between cyclic GMP, DNA synthesis, and chemical carcinogens. (19 refs)

79-0259 Identification of Four trans-3,4-Dihydrodiol Metabolites of 7,12-Dimethylbenz(a)anthracene and Their In Vitro DNA-binding Activities upon Further Metabolism. (Eng) Chou, M. W. (Dept. Pharmacology, Sch. Medicine, Uniformed Services Univ. Health Sciences, Bethesda, MD, 20014); Yang, S. K. *Proc Natl Acad Sci USA* 75(11): 5466-5470; 1978.

The trans-3,4-dihydrodiols of 7,12-dimethylbenz(a)anthracene (DMBA), 7-methyl-12-hydroxymethylbenz(a)anthra-

cene (7-Me-12-OHMeBA), 7-hydroxymethyl-12-methylbenz(a)anthracene (7-OHMe-12-MeBA), and 7,12-di(hydroxymethyl)benz(a)anthracene [7,12-(OHMe)₂BA] were identified as metabolites of the potent carcinogenic and adrenocorticolytic agent DMBA. The four trans-3,4-dihydrodiols were identified by their (1) UV-visible absorption and fluorescence properties, (2) different retention times on both reversed-phase and normal-phase high-pressure liquid chromatography, (3) mass spectra, and (4) inability to form vicinal cis-acetonides. Upon further metabolism by liver microsomes, the trans-3,4-dihydrodiols of DMBA, 7-Me-12-OHMeBA, and 7-OHMe-12-MeBA were found to give rise to products that bound more strongly to DNA in vitro than the products of 7,12-Me₂BA. The evidence suggests that one or more of the four trans-3,4-dihydrodiols may be the proximate carcinogenic and adrenocorticolytic metabolites. (41 refs)

79-0260 Induction of Malignant Transformation and Mutagenesis by Dihydrodiols Derived from 7,12-Dimethylbenz(a)anthracene. (Eng) Marquardt, H. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Baker, S.; Tierney, B.; Grover, P. L.; Sims, P. *Biochem Biophys Res Commun* 85(1): 357-362; 1978.

7,12-Dimethylbenz(a)anthracene (DMBA) and four of its trans-dihydrodiols: trans-3,4-dihydro-3,4-dihydroxy-DMBA (3,4-diol), trans-8,9-dihydro-8,9-dihydroxy-DMBA (8,9-diol), trans-10,11-dihydro-10,11-dihydroxy-DMBA (10,11-diol), and trans-5,6-dihydro-5,6-dihydroxy-DMBA (5,6-diol) were tested for their ability to induce mutations to 8-azaguanine resistance in V79 Chinese hamster cells and malignant transformation in M2 mouse fibroblasts. The concentrations tested ranged from 0.12 to 1 μ g/ml for all compounds except the 5,6-diol, which was tested at 1, 5, and 10 μ g/ml. The 3,4-diol and the 8,9-diol, but not DMBA, induced mutations in V79 cells; both diols were more active than the parent compound in inducing malignant transformation in the M2 cells. The 5,6-diol and the 10,11-diol were relatively inactive as mutagens or transforming agents. When cells from two transformed clones of the 3,4-diol were injected into six C3H/HcJ mice, all six mice developed sarcomas 5 wk later. This evidence is consistent with the theory that the vicinal diol-epoxides are the important species in activated, carcinogenic polycyclic hydrocarbons. (22 refs)

79-0261 Acetic Acid Pretreatment of Initiated Epidermis Inhibits Tumour Promotion by a Phorbol Ester. (Eng) Murray, A. W. (Sch. Biological Sciences, Flinders Univ. S. Australia, Bedford Park, S. Australia 5042, Australia). *Experientia* 34(11): 1507-1508; 1978.

A study was conducted to determine whether the cytotoxicity of compounds such as acetic acid could be an explanation for their inability to act as tumor promoters. Female Swiss

albino mice were initiated on the skin with 25 μ g 7,12-dimethylbenz(a)anthracene (DMBA). One week later, one group was treated 2x/wk with 167 micromoles (μ mol) acetic acid and another with 500 μ mol, for a total of five doses. All groups were then promoted with croton oil (0.2 ml of a 0.5% soln 2x/wk). Pretreatment of initiated skin with five 500- μ mol doses of acetic acid gave a tumor yield during promotion of 50% that of the control (DMBA + croton oil only) group. This decrease was probably not caused by interference with DMBA initiation, since acetic acid treatment was not begun until 1 wk after DMBA application. The simplest explanation is that acetic acid treatment killed a proportion of the initiated cells. Agents such as acetic acid may induce all of the biochemical changes in skin (ie, hyperplasia) necessary for promotion but do not assay as promoters because of cytotoxicity. The observation that not all hyperplastic agents act as tumor promoters does not eliminate the possibility that epidermal hyperplasia is a sufficient condition for promotion. (6 refs)

79-0262 Preparation, Isolation, Analysis, and Characterization of 3-Benzo(a)pyrenyl- β -D-glucopyranosiduronic Acid: A Metabolite of 3-Hydroxybenzo(a)pyrene with Potentially High Carcinogenic Activity. (Eng) Johnson, D. B. (Midwest Res. Inst., 425 Volker Blvd., Kansas City, MO, 64110); Engel, J. F.; Murrill, E. E.; Guire, P. E.; Barker, C. W.; Bardwell, C. M.; Shan, A. Y.; Swanson, M. J.; Stone-Heurner, J. G. *Anal Biochem* 91(1): 138-145; 1978.

3-Hydroxybenzo(a)pyrene (3OH-BP; 1.0 mM) was converted to its glucuronide, 3-benzo(a)pyrenyl- β -D-glucopyranosiduronic acid (BGA), by incubation with 25 mg freeze-dried rabbit liver microsomes, 2.0 ml of 0.1 M tris(hydroxymethyl)aminomethane-HCl, 0.002 M $MnCl_2$, 0.01% Triton X-100, 5.0% ethanol, and 3.75 mM uridine 5'-diphosphoglucuronic acid. The reaction was monitored by fluorimetry and reverse-phase, paired-ion, high-pressure liquid chromatography (HPLC). Fluorescence loss was linear up to 120 min. HPLC of the reaction mixture gave a retention time of 5.1 min for the glucuronide peak and 36.5 min for the 3OH-BP peak with 70% methanol and 30% water as eluants. Proof of the existence of BGA was supplied by radiotracer analysis with tritium and enzymatic hydrolysis with β -glucuronidase, with both techniques utilizing HPLC. Field desorption and direct inlet mass spectral techniques were used to characterize BGA. All these methods should be readily adaptable to other glucuronide conjugates of polynuclear aromatic hydrocarbons. (10 refs)

79-0263 Serum Haptoglobin Levels in Mice with 7,12-Dimethylbenz(a)anthracene-induced Tumors. (Eng) Palmer, W. G. (NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Ulland, B. M. *Oncology* 35(5): 220-223; 1978.

Serum haptoglobin (Hp) levels were determined periodically during a 24-wk period in mice treated with 7,12-dimethylbenz(a)anthracene (DMBA; 28.5 mg/kg 1x/wk for 12 wk). Thirty of 45 mice treated with DMBA developed tumors by the end of 24 wk. Thirteen of the 15 tumor-bearing males had lymphocytic lymphomas, but 12/15 tumor-bearing females had mammary carcinomas. Hp levels were normal in 448/460 serum samples collected before 10 wk, during which time there was no evidence of tumors. This indicates that DMBA itself does not affect serum Hp concentrations. Nine of the 15 DMBA-treated mice that did not develop tumors had either normal or minimally elevated Hp levels throughout the 24-wk period. Animals with lymphomas had only minimal or moderate elevations in serum Hp, whereas mice bearing mammary carcinomas and gastric squamous cell carcinomas had high Hp levels that remained elevated during most of the tumor development period. In most mice with mammary carcinomas, the initial rise in serum Hp coincided closely with the first appearance of a palpable mass. These findings indicate that serum Hp levels in animals with DMBA-induced tumors are related to tumor type. In the absence of hemolytic or nonmalignant inflammatory conditions, the Hp response to a tumor may be a reflection of its inflammatory characteristics. (18 refs)

79-0264 Transmaternal Modification of the Berenblum/Mottram Experiment in Mice. (Eng) Schweizer, J. (Inst. Experimental Pathology, German Cancer Res. Center, In Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Loehrke, H.; Goertler, K. *Bull Cancer (Paris)* 65(3): 265-270; 1978.

In a modification of the classic two stage initiation-promotion (I-P) carcinogenesis experiment, NMRI mice experienced a significantly greater number of tumors when treated topically 2x/wk for 24 wk with 10 nanomoles 12-O-tetradecanoylphorbol-13-acetate (TPA) after in utero initiation with 7,12-dimethylbenz(a)anthracene (DMBA) given intragastrically to the pregnant mothers. Six groups of mothers received DMBA in 60-150 mg/kg total doses divided into four or five parts over 3- or 4-day periods between days 14 and 21 of gestation. There were 17 abortions in 49 treated mice, but the total number of offspring in treatment and control groups was only slightly different, and all surviving offspring were originally tumor free. Fibroepitheliomas began appearing in all I-P groups 5-9 wk after TPA treatment, and the number of tumor bearing animals increased over time. No papillomas were noted in noninitiated or initiated but not promoted animals over the duration of the experiment. Initiation at 14-18 days of gestation produced the lowest percentage of animals with tumors, initiation at 16-19 days the highest percentage, and later initiation led to a gradual decrease in tumor-bearing animals. The number of tumors/animal followed a similar distribution with respect to time of in utero treatment. Thirty-five animals receiving a total of 60 mg TPA in four doses between days 16 and 19 developed a total of 43 malignant and 55 benign tumors not only of the skin but of lung,

liver, ovaries, mammary glands, vagina, lymph nodes, thymus, and the blood cell system. It is suggested that these findings have direct implications for maternal exposure to subthreshold doses of carcinogen in human pregnancy. (10 refs)

79-0265 Characteristics of Chemically Transformed Mouse Epidermal Cells In Vitro and In Vivo.

(Eng) Fusenig, N. E. (German Cancer Res. Center, Im Neuenheimer Feld 280, D 6900 Heidelberg, W. Germany); Amer, S. M.; Boukamp, P.; Worst, P. K. *Bull Cancer (Paris)* 65(3): 241-247; 1978.

Primary cultures of epidermal cells from newborn mouse skin proliferated and expressed typical epidermal functions for a limited time in vitro. The cultured cells had the features of keratinizing cells, and they exhibited strong reactivity with an epidermis-specific membrane antiserum. These cells were transformed by dimethylbenz(a)anthracene (DMBA) in standard cultures or, more easily, in cultures using 3T3 feeder cells. The transformed cells had an increased proliferation rate, did not pile up or form multilayered cultures like their normal counterparts, and exhibited less keratinization. When the transformed cells were grown in air on collagen gels, they formed irregular clumps with central (horn-pearl) keratinization, whereas normal controls formed stratified structures. The transformed cells exhibited reduced reactivity with tissue-specific membrane antiserum: there was masking or rearrangement of the membrane antigens, with simultaneous exposure of new fetallike antigens. Their reactivity with histocompatibility antisera was reduced only slightly. These cells had both numerical and structural chromosome aberrations. They grew in soft agar, and they induced tumors upon sc injection in syngeneic or allogeneic hosts. When transplanted as cultures (on collagen) or as suspensions, the transformed cells formed epithelial cell cords that invaded the underlying mesenchyme. This growth behavior was typical of an invasive carcinoma. Cell cultures derived from in vivo DMBA-induced tumors behaved like in vitro carcinogen-transformed cells. (27 refs)

79-0266 Effect of Neonatal Administration of Sex Steroids on 7,12-Dimethylbenz(a)anthracene-induced Mammary Carcinoma and Dysplasia in Female Sprague-Dawley Rats. (Eng) Yoshida, H. (First Dept. Pathology, Sch. Medicine, Ehime Univ., Shizukawa, Shigenobu-cho, Onsen-Gun, Ehime-ken 791-02, Japan); Fukunishi, R. *Gann* 69(5): 627-631; 1978.

The effect of neonatal administration of various sex steroids to female Sprague-Dawley rats on the induction of 7,12-dimethylbenz(a)anthracene (DMBA)-induced mammary carcinoma and dysplasia was examined. Two-day-old rats were inoculated sc with 1.25 mg testosterone propionate (TSP), 1.0 mg 5 α -dihydrotestosterone (DHT), 0.1 mg 17 β -estradiol

(ED), or 1.0 mg progesterone (PG). All rats were given 20 mg DMBA via stomach tube at 50 days of age and then sacrificed at 300 days of age. In TSP- or ED-treated rats, lactation in the mammary gland and an absence of corpora lutea were found. The induction of mammary carcinoma was strongly suppressed, but the induction of mammary dysplasia was significantly accelerated in these rats. DHT and PG had no effect on the induction of mammary carcinoma or dysplasia. The absence of corpora lutea in the ovaries or a PG deficiency might have played an important role in the suppression of mammary carcinogenesis. (25 refs)

79-0267 Cytochrome P-450 in a Cultured Human Lymphocyte Cell Line. (Eng) Gurtoo, H. L. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., Buffalo, NY, 14263); Marinello, A. J.; Freedman, H. J.; Paigen, B.; Minowada, J. *Biochem Pharmacol* 27(22): 2659-2662; 1978.

Aryl hydrocarbon hydroxylase (AHH) activity and inducibility were studied in a cultured human lymphocyte cell line, RPMI-1788. The cells were incubated for 48 hr before addition of one of the following AHH inducers: dibenzanthracene (DBA: 0.3 μ M), benzantracene (10.0 μ M), 3-methylcholanthrene (MC: 1.0 μ M), or 2,3,7,8-tetrachlorodibenzo-p-dioxin (0.3 nM). AHH activity, measured 24 hr later, had increased 160%-350% over control values. The difference spectra of microsomes isolated from DBA-induced RPMI-1788 cells and from the liver of rats pretreated with phenobarbital (PB) and MC were compared. As in previous reports, difference spectral maxima of liver microsomes from PB- and MC-treated rats were at 450 and 448 nanometers (nm), respectively. The difference spectral max of the RPMI-1788 cell microsomes was at 451 nm. The spectral examination reveals, therefore, that the mixed-function oxygenase-linked cytochrome in RPMI-1788 is distinct from that in rodents. It is suggested that mechanistic, physical, and biochemical information obtained from studies with rodent liver cytochromes P-450 may not be directly applicable to humans. (14 refs)

79-0268 The Effect of Dinitrochlorobenzene (DNCB) on Dimethylbenzanthracene (DMBA) Carcinogenesis on Hamster Buccal Pouch. (Eng) Murphy, J. B. (Dept. Oral Pathology, Tufts Univ. Sch. Dental Medicine, One Kneeland St., Boston, MA, 02111); Giunta, J. L. *Oral Surg* 46(5): 669-675; 1978.

The effect of dinitrochlorobenzene (DNCB) on dimethylbenzanthracene (DMBA)-induced carcinogenesis of the Syrian hamster buccal pouch was studied. Hamsters were treated with 2% DNCB (applied topically 2x/wk for 2 wk) followed by 0.5% DMBA (applied topically 3x/wk for 10 wk). Controls were treated with DNCB alone or DMBA alone. The histologic characteristics and latent periods of the epidermoid

carcinomas induced by DMBA were not altered by prior treatment with DNCB. However, there was a sensitization of the buccal pouch in animals painted with DNCB, with both gross and histologic evidence of a delayed sensitivity reaction being demonstrated. The data suggest that the cellular response against tumor cells is dependent on specific tumor antigens that are probably very weak in this chemical carcinogenesis system. (11 refs)

- 79-0269** **Mutagenesis and Cell Transformation of Mammalian Cells in Culture by Chemical Carcinogens.** (Eng) Huberman, E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *J Environ Pathol Toxicol* 2(1): 29-42; 1978.

The relationship between mutagenesis and carcinogenicity was studied by testing a series of 11 polycyclic hydrocarbons with different degrees of carcinogenicity in a cell-mediated mutagenesis assay for the induction of ouabain-resistant mutants. Four carcinogens [7,12-dimethylbenz(a)anthracene benzo(a)pyrene (BP), 3-methylcholanthrene and 7-methylbenz(a)anthracene] induced ouabain-resistant mutants, whereas five noncarcinogens were not mutagenic. The 7,8-diol-9,10-epoxide of BP was identified as its major mutagenic and cell-transforming metabolite. Based on the finding that the same metabolites are responsible for cell transformation and mutagenesis in mammalian cells, it was possible to estimate the genetic target size for transformation. This was done by comparing in the same cells (normal golden hamster embryo cells) the frequency of cell transformation and mutation for ouabain resistance (presumably due to mutation at one locus) induced by BP and its (\pm)-trans-7,8-diol. The ratio between cell transformation and mutagenesis for ouabain resistance induced by either hydrocarbon was 20:1, indicating that the target size for transformation is 20 times larger than that determined for ouabain resistance. Therefore, cell transformation may be due to a mutation and this mutation may occur in one out of a small number of the same or different genes. (65 refs)

- 79-0270** **Role of Functional Activity of Connective Tissue in Chemical Carcinogenesis of the Mammary Gland.** (Ukr) Turkevich, N. M. (Inst. Problems Oncology, Kiev, USSR); Vasnetsova, S. S.; Gutnik, N. S.; Matveichuk, Ia. D. *Dopov Akad Nauk Ukr RSR B* (9): 847-849; 1978.

The role of decreased functional activity of the connective tissue caused by various endocrine disorders on the development of 7,12-dimethylbenz(a)anthracene (DMBA)-induced tumors of the mammary glands was evaluated. Random-bred albino rats were inoculated iv with 6 mg DMBA. The animals were then divided into three groups: Group 1 rats underwent transplantation of a homologous hypophysis 2 wk after DMBA exposure; Group 2 rats underwent ovariectomy 25

days after exposure; Group 3 rats underwent sham ovariectomy. Breast tumors were detected in 31/45 rats in Group 1, 0/27 rats in Group 2, and 13/31 rats in Group 3; the av latent period of tumor development in Groups 1 and 3 was 51 and 49 days, respectively. (5 refs)

- 79-0271** **Stimulation of DNA Synthesis by Tumour Promoter and Pure Mitogenic Factors.** (Eng) Dick-er, P. (Imperial Cancer Res. Fund Labs., Lincoln's Inn Fields, London WC2, England); Rozengurt, E. *Nature* 276(5689): 723-726; 1978.

Studies were carried out in mouse and human fibroblast cultures to determine the significance of the serum dependence of the growth-stimulating activity of 12-O-tetradecanoylphorbol-13-acetate (TPA). In synthetic, serum-free medium, TPA interacted synergistically with insulin, epidermal growth factor (EGF), and fibroblast-derived growth factor (FDGF) in stimulating ^3H -thymidine incorporation into acid-precipitable material by quiescent cultures of mouse 3T3 cells. EGF and TPA reproducibly increased DNA synthesis considerably in eight independent experiments, although the magnitude of the increase varied. In the presence of a fixed concentration of insulin, TPA stimulated DNA synthesis in a dose-dependent manner. The lowest concentration of TPA needed to show synergism consistently with 1 $\mu\text{g}/\text{ml}$ of insulin was 5 nanograms/mg. Only 20 min of exposure to the promoter was sufficient to render the cultures sensitive to the mitogenic effect of insulin, EGF, or FDGF. The results indicate that there is a striking synergistic interaction between TPA and growth factors in stimulating DNA synthesis in quiescent cultures of mouse and human fibroblasts maintained in serum-free medium. The possibility that promotion in vivo can be induced by an interaction between the promoter and growth factors should receive serious consideration. (16 refs)

- 79-0272** **Catabolism of 2-Deoxyglucose by Phagocytic Leukocytes in the Presence of 12-O-Tetradecanoyl Phorbol-13-acetate.** (Eng) Zabos, P. (Dept. Pediatrics, Mount Sinai Medical Center, 1 Gustave L. Levy Place, New York, NY, 10029); Kyner, D.; Mendelsohn, N.; Schreiber, C.; Waxman, S.; Christman, J.; Acs, G. *Proc Natl Acad Sci USA* 75(11): 5422-5426; 1978.

Data indicating that 12-O-tetradecanoylphorbol-13-acetate (TPA) dramatically increases the rate of decarboxylation of 2-deoxyglucose (2-dGlc) by granulocytes, monocytes, and macrophages are presented. In the presence of 10 nanograms/ml TPA, human granulocytes, monocytes, mouse macrophages, and HL-60 cells (a line established from a patient with acute myeloid leukemia) released greatly increased amounts of carbon-1 (as $^{14}\text{CO}_2$) from ^{14}C -labeled 2-dGlc and glucose. These cells released barely detectable amounts of CO_2 in the absence of TPA. In contrast, T lymphocytes, B lym-

phocytes, RBC, and platelets released low levels of CO₂ in both the presence and absence of TPA. In the granulocytes, there was concurrent intracellular accumulation of a phosphorylated 5-carbon intermediate. Chromatographic analysis of the intracellular pool revealed the presence of 2-dGlc 6-phosphate, 2-deoxygluconic acid 6-phosphate, and the phosphorylated compound, which reacted with phenylhydrazine. This finding suggests that the mechanism of 2-Glc catabolism in the presence of TPA is analogous to the catabolism of glucose via the hexose monophosphate shunt. Several lines of evidence indicate that enzymes of this shunt are able to mediate the oxidative decarboxylation of 2-dGlc. Phorbol didecanoate, which also possesses inflammatory and tumor-promoting activity, and mezerein, which resembles TPA in its ability to inhibit cell differentiation and enhance plasminogen activator production, also increased CO₂ release. (28 refs)

- 79-0273 Hepatic Mixed-Function Oxidase Activity in Rainbow Trout Exposed to Several Polycyclic Aromatic Compounds.** (Eng) Gerhart, E. H. (Dept. Chemistry, Univ. Minnesota, Duluth, MN, 55812); Carlson, R. M. *Environ Res* 17(2): 284-295; 1978.

The effects of polycyclic aromatic hydrocarbons (PAH) on microsomal liver enzymes were examined in rainbow trout. Various PAH were injected ip to screen for mixed-function oxidase (MFO) activity. Chrysene, benzo(a)pyrene (BP), and Aroclor 1254 induced MFO activity. When fish were also exposed to solubilized pyrene, fluoranthene, and BP in water, a bioaccumulation of BP resulted in MFO induction, whereas a bioaccumulation of pyrene and fluoranthene did not. Based on the results of water and injection exposure to BP, it was predicted that tissue concentrations in excess of 300 µg/kg BP would be accompanied by MFO induction in rainbow trout. (36 refs)

- 79-0274 Effect of Selective T Cell Depletion in Modulating the Behaviour of Fibrosarcomas in Mice.** (Eng) Gupta, S. (Dept. Pathology, Postgraduate Inst. Medical Education and Res., Chandigarh-160012, India); Sehgal, S.; Aikat, B. K. *Indian J Med Res* 68: 300-305; 1978.

The role of selective T-cell depletion in inducing metastases of methylcholanthrene (MCA)-induced fibrosarcomas was studied in C57 mice. T-cell depleted mice were produced by thymectomy at 3 wk, followed by 850 R of irradiation and repopulation with 2 x 10⁶ cells from syngeneic bone marrow. Sc injection of 10⁶ MAC-induced fibrosarcoma cells induced a large localized tumor in normal animals within 10 days with no visceral metastases; 2/15 animals showed metastases in the axillary nodes. In the T-cell depleted mice, injection of 10⁶ fibrosarcoma cells induced 13 metastases in 7/15 animals, ie, in the lung (5), axillary node (4), right inguinal lymph node (2), and peritoneal cavity (2). There was no significant differ-

ence in the latent period or in tumor size between the T-cell depleted and control animals. It is concluded that a significant proportion of T-cell depletion favors the development of visceral metastases in C57 mice, while such metastases are not found in fully immunocompetent animals. (24 refs)

- 79-0275 Induction of Aryl Hydrocarbon Hydroxylase by 3-Methylcholanthrene in Liver, Lung and Kidney of Gonadectomized and Sham-operated Wistar Rats.** (Eng) Warren, P. M. (Div. Pharmacology and Toxicology, Faculty Pharmaceutical Sciences, Univ. British Columbia, Vancouver, B.C., V6T 1W5, Canada); Bellward, G. D. *Biochem Pharmacol* 27(21): 2537-2541; 1978.

Dose-response curves were obtained for the induction of aryl hydrocarbon hydroxylase (AHH), measured as benzpyrene hydroxylase, in liver, lung, and kidney by the administration of methylcholanthrene (MC; 0-40 mg/kg ip) in Wistar rats. Lung was the tissue most sensitive to induction, followed by liver and then kidney. Although liver exhibited the greatest overall activity, the percent increase over control AHH levels was much higher in the two extrahepatic tissues. There were no significant differences in the AHH activities of sham and ovariectomized females in any of the tissues at the control levels or after MC treatment. However, castration of the males decreased liver enzyme levels and increased kidney enzyme levels in controls. The AHH levels achieved after maximal MC induction were the same in the livers of castrated and in sham-operated male rats. Significantly increased maximal induction was observed in the kidney following MC administration in castrated males. These results indicate that local effects of toxic metabolites formed in such areas as the lung are likely to be of importance in tumor induction. (38 refs)

- 79-0276 Influence of Transplacental 3-Methylcholanthrene on Aryl Hydrocarbon Hydroxylase Activity of Mouse Lung.** (Eng) Hunt, W. G. (Dept. Pharmacology, Univ. Vermont, Burlington, VT); Knight, S. E.; Soyka, L. F. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 999-1014; 1977.

To determine whether perinatal exposure to 3-methylcholanthrene (3-MC) produces changes in the lung's ability to metabolize or detoxify polycyclic hydrocarbons, pregnant outbred Swiss-Webster mice were treated with 4 mg 3-MC in oil sc on 2 successive days prior to delivery. Lung aryl hydrocarbon hydroxylase (AHH) activity in the offspring was studied as a function of age, sex, strain, and inducibility. Lung AHH peaked at a higher level and decreased more rapidly with age in males than in females. AHH activity was four

CHEMICAL CARCINOGENESIS

times higher in 10-day-old treated male and female offspring than in controls, but at 20 days this difference was no longer statistically significant. The magnitude of the responses to induction by 3-MC pretreatment (300%-600%) did not differ significantly from controls, compared with 3-MC-exposed mice of either sex. In studies of strain differences, basal AHH levels at 20 days of age were lower for (DBA/1J x SWR) F_1 mice than for Swiss-Webster, C57BL/6J, and (C57BL/6J x C3H/HeJ) F_1 mice. Females had higher basal levels than males at 10 wk in the SWR/J and (C57BL/6J x C3H/HeJ) F_1 strains and lower levels than males in the C57BL/6J mice. The induction ratio was greater for all strains in the 10-wk-old mice than for neonates, although absolute levels at these two ages were identical. Foster studies showed that lung AHH levels were elevated to a greater extent by exposure to 3-MC and its metabolite in the milk than via the transplacental route. Pre- and/or postnatal exposure to carcinogens could influence the manner in which adults respond to reexposure to the same or related compounds. (16 refs)

- 79-0277 Time Course of the Induction of Aryl Hydrocarbon Hydroxylase in Rat Liver Nuclei and Mitochondria by Phenobarbital, 3-Methylcholanthrene, 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin, Dieldrin and Other Inducers.** (Eng) Viviani, A. (Inst. Toxicology, Federal Inst. Technology, CH-8603 Scherzenbach, Switzerland); Lutz, W. K.; Schlatter, C. *Biochem Pharmacol* 27(17): 2103-2108; 1978.

The time course of the induction of aryl hydrocarbon hydroxylase (AHH) was measured in male liver nuclei and mitochondria after treatment of adult animals (Sprague-Dawley-derived SIV 50 strain) with various inducers for up to 14 days. After daily ip injection of 3-methylcholanthrene (MC, 20 mg/kg), the nuclear activity increased to a max of 600% of the control activity after 4 days, whereas the mitochondrial activity was 400% of the control activity at the same date. After 12 days, both activities equilibrated at 400%. A similar time course was found after a single ip injection of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (0.01 mg/kg) with an induction of 500% and 300% for nuclei and mitochondria, respectively, after 2 days, and to 400% for both after 12 days. Phenobarbital (PB) was given continuously in the drinking water (1 g/liter); it induced mitochondrial activity to 200% after 8 days and 170% after 14 days. The nuclear activity was only slightly induced to a constant level of 130% between days 8 and 14. Dieldrin did not significantly increase the mitochondrial activity after daily ip injection (20 mg/kg), but the nuclear activity was raised to 200% after 3 days, and lowered to control values after 12 days. Other inducers tested were benz[a]anthracene (BA), hexachlorobenzene (HCB), and 1,1,1-trichloro-2,2-bis(*p*-chlorophenyl)ethane (DDT). The induction pattern with BA was similar to that of MC, a model compound for the group of cytochrome P-448 inducers. The induction by HCB and DDT resembled that by PB, a typical cytochrome P-450 inducer. The results indicate that long-term treatment results in an equal relative induction of

AHH activity in mitochondria and nuclei and that only the absolute value of the induction is dependent on the inducer used. (29 refs)

- 79-0278 The Influence of Phenobarbital, 3-Methylcholanthrene, and 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin on Glutathione S-Transferase Activity of Rat Liver Cytosol.** (Eng) Baars, A. J. (Dept. Pharmacology, Univ. Leiden, Subfaculty Pharmacy, Sylvius Labs., Wassenaarseweg 72, Leiden, Netherlands); Jansen, M.; Breimer, D. D. *Biochem Pharmacol* 27(21): 2487-2494; 1978.

The influence of the drug-metabolizing enzyme inducers, phenobarbital (PB), 3-methylcholanthrene (MC), and 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) on glutathione (GSH) S-transferase activity in rat liver cytosol was studied using styrene oxide (STOX), 1,2-butylene oxide (BOX), and 1-chloro-2,4-dinitrobenzene (CDNB) as the electrophilic substrates. Assuming Michaelis-Menten kinetics, apparent K_m and V_{max} values of the GSH S-transferase activities were calculated using a computer program. Pretreatment of the rats with MC (20 mg/kg ip 1x/day for 4 days) resulted in enhancement of all measured activities expressed in terms of cytosol protein, while TCDD administration (10 μ g/kg ip 1x/day on days 1 and 7) enhanced only the activities expressed on a per gram body wt basis. PB administration (80 mg/kg ip 1x/day for 14 days) enhanced activities by both standards when STOX was the substrate, but when CDNB was the substrate, only the activity per gram body wt increased. All pretreatments increased the V_{max} values when CDNB was the substrate, while PB and MC had enhancing effects when STOX was the substrate. The V_{max} with BOX as substrate was enhanced only after TCDD administration. The K_m values when BOX was the substrate were lowered after MC pretreatment. TCDD pretreatment decreased the K_m for the STOX substrate, while it increased the K_m for the CDNB substrate. It is concluded that the GSH S-transferase system is inducible. Qualitative differences were not observed between the inducing effects of PB and MC; however, TCDD administration resulted in a different induction pattern, which may indicate that induction with this latter agent involves different forms of GSH S-transferases. (42 refs)

- 79-0279 Effect of Typical Inducers of Microsomal Drug-Metabolizing Enzymes on Phospholipid Metabolism in Rat Liver.** (Eng) Ishidate, K. (Medical Res. Inst., Tokyo Medical and Dental Univ., Kanda-Surugadai, Chiyoda-ku, Tokyo 101, Japan); Yoshida, M.; Nakazawa, Y. *Biochem Pharmacol* 27(22): 2595-2603; 1978.

The effect of pretreatment with phenobarbital (PB; 80 mg/kg/day po), polychlorinated biphenyls (PCB; 100 mg/kg/day po), and 3-methylcholanthrene (3-MC; 50 mg/kg/day ip) on the metabolism of phospholipids in liver was studied in male Wistar rats. PB, PCB, or 3-MC was given

on two successive days. On the third day, animals were injected ip with (^{32}P)orthophosphate (200-250 μCi) or ($\text{Me-}^{14}\text{C}$)choline chloride (3.8 μCi) and killed 1 hr later. PB had no significant effect on the incorporation of ^{32}P into liver microsomal phospholipid but the rate of incorporation of (^{14}C) choline into phosphatidylcholine (PC) in both subcellular components of the liver and blood plasma decreased slightly. The ratio of (^{14}C) specific activity of phosphorylcholine to that of microsomal phospholipid was considerably higher in PB-treated rats compared with the ratio in control rats. These and previous findings suggest that proliferation of liver endoplasmic reticulum membranes induced by PB would be accompanied by the stimulation of phospholipid synthesis at early times followed by a decrease in the turnover rate of microsomal phospholipids. The administration of PCBs caused strong inhibition of both ^{32}P and ^{14}C incorporation into PC in liver subcellular fractions. The secretion of PC from liver cells into blood plasma was also strongly depressed as was phospholipid catabolizing activity in the liver. The decrease in ^{32}P incorporation into liver microsomal PC was also observed in rats treated with 3-MC. The mechanism of the observed inhibitions remains to be elucidated. (54 refs)

79-0280 Model Quantum-Chemical Studies on the Reaction Between the Candidate Proximate Carcinogen Benzo(a)pyrene-7,8-dihydrodiol-9,10-epoxide and Guanine. (Eng) Lavery, R. (Institut de Biologie Physico-Chimique, Laboratoire de Biochimie Theorique associe au C.N.R.S., 13, rue P. et M. Curie, 75005 Paris, France); Pullman, A.; Pullman, B. *Int J Quant Chem Quant Biol Symp* (5): 21-34; 1978.

A model involving "bay-region" diol epoxides as possible proximate metabolites for polycyclic aromatic hydrocarbons that form adducts with the bases of cellular nucleic acids is presented. The mechanism by which these adducts are formed is hypothesized to consist of an electrophilic substitution on the NH_2 group of guanine by a carbonium ion derived from the opening of an epoxide. It involves the formation of a quaternary intermediate followed by hydroxyl-assisted deprotonation. (19 refs)

79-0281 Mutagenicity of Optically Pure (-)trans-7,8-Dihydroxydihydrobenzo(a)pyrene. (Eng) Nagao, M. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukuba, Chuo-ku, Tokyo 104, Japan); Sugimura, T.; Yang, S. K.; Gelboin, H. V. *Mutat Res* 58(2/3): 361-365; 1978.

The mutagenicity of the (+) and (-) enantiomers of trans-7,8-dihydroxy-7,8-dihydrobenzo(a)pyrene (trans-7,8-diol), their di(-)methoxyacetates, and the hydrolysis and reduction products of two diol-epoxide derivatives of benzo(a)pyrene (BP) were tested using *Salmonella typhimurium* strains TA100 and TA98 with and without rat liver microso-

mal activation. The (-)trans-7,8-diol was strongly mutagenic to TA100 in the absence of microsomal activation while the (+)trans-7,8-diol was weakly mutagenic. Microsomal activation enhanced the number of revertants in TA100 1.5-fold at doses of 4-6 $\mu\text{g}/\text{plate}$ with the (-)trans-7,8-diol. The (-)trans-7,8-diol was not mutagenic to TA98 in the absence of the microsomal preparation but weakly mutagenic with activation. With activation, the (+)enantiomer was a much stronger mutagen in TA98 than was the (-)enantiomer. The di(-)methoxyacetates of both (+)- and (-)-trans-7,8-diols were not mutagenic to TA100 or TA98 with or without activation. Of the hydrolysis and reduction products of the diol-epoxide derivatives tested, the (7/8,9)-triol and (7,9/8) triol were very weakly mutagenic to TA100 with activation. None of the tetrols was mutagenic to TA100 or TA98 with or without activation. These results suggest that the (-)trans-7,8-diol and the (+)trans-7,8-diol can exhibit mutagenic activity with microsomal activation. The (-)trans-7,8-diol may be a direct mutagen. (16 refs)

79-0282 Antioxidants and the Mutagenicity of Benzo(a)pyrene and Some Derivatives. (Eng) Calle, L. M. (Dept. Chemistry, Ohio Univ., Athens, OH, 45701); Sullivan, P. D.; Nettleman, M. D.; Ocasio, I. J.; Blazyk, J.; Jollick, J. *Biochem Biophys Res Commun* 85(1): 351-356; 1978.

The effects of antioxidants on the mutagenicity of benzo(a)pyrene (BP), 6-methylbenzo(a)pyrene (6-MeBP), and 10-methylbenzo(a)pyrene toward *Salmonella typhimurium* strain TA98 were determined. In the Ames mutagenicity assay, 6-MeBP and 10-MeBP were approx six and two times more mutagenic than BP, but 6-methoxybenzo(a)pyrene and 7,10-dimethylbenzo(a)pyrene were considerably less active than BP. The antioxidants phenazine methosulfate, phenothiazine, 2,3,6,7-tetramethoxythianthrene, ethoxyquin, 4-hydroxy-2,2,6,6-tetramethylpiperidinoxy, Irganox 1010, 3,3',5,5'-tetra-*t*-butyl-4,4'-biphenol, Ethyl 736, butylated hydroxytoluene, and butylated hydroxyanisole inhibited mutagenic capabilities when added at antioxidant/hydrocarbon ratios of approx 10, 60, and 20 for BP, 6-MeBP, and 10-MeBP, respectively. (31 refs)

79-0283 Electric Linear Dichroism Study on the Orientation of Benzo[a]pyrene-7,8-dihydrodiol 9,10-Oxide Covalently Bound to DNA. (Eng) Geacintov, N. E. (Dept. Chemistry, Radiation and Solid State Lab., New York Univ., New York, NY, 10003); Gagliano, A.; Ivanovic, V.; Weinstein, I. B. *Biochemistry* 17(24): 5256-5262; 1978.

The electric linear dichroism spectra of native calf thymus DNA modified to a small extent by reaction with (\pm)-7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene (BPDE) were measured, as were the spectra of physical complexes of benzo(a)pyrene (BP) and proflavine (PF) with DNA. The linear dichroism δA of the covalent BPDE-DNA

complex in the wavelength region of the absorption of the pyrenelike BPDE chromophore was positive. In contrast, δA was negative in the absorption region of the DNA bases, as well as in the absorption region of the BP and PF molecules physically bound to DNA. It is concluded that the orientation of the BPDE moiety is not of the intercalation type, as is the case for the physical BP and PF complexes. The reduced linear dichroism was wavelength dependent for the BPDE-DNA and BP-DNA complexes, which indicated that there is a heterogeneity of binding sites with different orientations. There appears to be one major type of oriented BPDE covalently bound to DNA. The long axis of the pyrenelike chromophore of BPDE lies on the surface of a cone whose axis is that of the DNA helix and whose angle, with respect to this axis, is ≤ 35 degrees. The planes of BP and PF were nearly parallel to the planes of the DNA bases. (27 refs)

79-0284 Polycyclic Hydrocarbon-induced Rat Sarcomas Correlated to Disturbances in the Deoxyadenylate Regions of the Tumor DNAs. (Eng) Pero, R. W. (Dept. Nucleic Acid Biochemistry, Lund Univ., Wallenberg Lab., Fack 7031, 220 07 Lund, Sweden); Bryngelsson, T.; Rudnick, C.; Levan, G. *Eur J Cancer* 14(9): 961-969; 1978.

An attempt was made to correlate polycyclic hydrocarbon-induced rat sarcomas to disturbances in the deoxyadenylate regions of the tumor DNA's. Inbred Wistar-Furth rats (8-35 days of age) were inoculated sc with 1- to 4-mg doses of benzo(a)pyrene (BP), 20-methylcholanthrene (MC), or 7,12-dimethylbenz(a)anthracene (DMBA). Tumors developed to a 100% incidence, and they were harvested 6-8 wk after they were palpable (< 7 mo). Ten separate tumor groups containing a total of 51 rat sarcomas were examined for agent-related abnormalities in their DNA's. The levels of deoxyadenylate (dA) regions in normal and tumor rat DNA's were estimated by annealing ^3H -polyuridylic acid to DNA and treating the resultant hybrids with ribonuclease A. All the tumor material had significant reductions in the dA regions of their DNA's when the levels were compared with normal rat DNA. Although the dA reductions were heterogeneous from one tumor group to the other, irrespective of the inducing agent, the greatest decreases tended to occur with tumors induced by MC and DMBA. No relationship was found between dA alterations and types of chromosomal aberrations in the tumor cell populations. However, normal and tumor DNAs, fractionated into adenine + thymine (A + T)-rich and guanine + cytosine (G + C)-rich DNA by thermal elution from hydroxyapatite columns, showed specific neoplastic-associated dA disturbances in the A + T-rich DNA of tumors induced by BP, MC, and DMBA. The base compositions of the tumor material were also analyzed and compared with normal rat DNA. Tumors induced by DMBA showed highly significant decreases in percent A + T, whereas BP- and MC-induced tumors tended to show only small increase in percent A + T. Some tumors induced by BP, MC, and DMBA were unaltered in base composition. The results are consistent with the hypothesis that DMBA is the strong-

est carcinogen in the series because it interacts preferentially with A + T-rich DNA, which is the type of DNA most important for polycyclic hydrocarbon-induced neoplasms in the rat. (31 refs)

79-0285 Effect of Benzene and Benzo(a)pyrene on Protein Synthesis in Isolated Nuclei and Chloroplasts. (Rus) Durmishidze, S. V. (Inst. Plant Biochemistry, Tbilisi, USSR); Dzhokhadze, D. I. *Dokl Akad Nauk SSSR* 242(2): 453-456; 1978.

The effect of benzene and benzo(a)pyrene (BP) on protein synthesis was studied in nuclei isolated from rat liver, and in nuclei and chloroplasts isolated from the leaves of 7- to 9-day-old pea plants. The intensity of protein synthesis was measured by the rate of ^{14}C -leucine incorporation. Incubation of the samples with benzene (at a ratio of 25 μl /50-100 μg DNA) resulted in stimulation of protein synthesis by 9%-31%. BP-induced stimulation of protein synthesis in leaf and liver nuclei was observed at a ratio of 3-4.5 μg BP/100 μg DNA and 1.5-3.0 μg BP/100 μg DNA, respectively (by 5%-27% and 3%-28%, respectively); in the chloroplasts, a stimulation of protein synthesis by 12%-27% was observed at a ratio of 1.5 μg BP/100 μg DNA. 79-0286 DNA-Carcinogen Interactions. (Eng) Dipple, A. (NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Baird, W. M.; Bigger, C. A.; Moschel, R. C.; Andrews, A. W. In: *Structural Correlates of Carcinogenesis and Mutagenesis. A Guide to Testing Priorities? Proceedings of the Second Food and Drug Administration Office of Science Summer Symposium held in Annapolis, 31 August-2 September 1977*. Office of Science, FDA (Annapolis, MD) HEW Publication No. (FDA)78-1046: 241 pp.; 4-7; 1978.

Chemical analysis of products of the reaction between carcinogenic polycyclic hydrocarbons and DNA has elucidated the mechanisms involved in the activation of two such carcinogens, benzo(a)pyrene and 7,12-dimethylbenz(a)anthracene (DMBA). Whereas structure-activity studies had focused attention on the K-region oxides of these compounds with misleading results, chemical analysis revealed that the metabolites of carcinogenic importance were the diol-epoxides. The binding of DMBA to DNA was studied in *Salmonella* in the presence of a rat liver S-9 or microsomal fraction. However, reproducible nucleoside-DMBA adducts from the *Salmonella* DNA were not obtained. DMBA-DNA binding has also been studied in mouse embryo cells and in mouse skin in vivo. Chromatograms of the adducts from the mouse embryo cells and from the mouse skin in vivo are essentially superimposable. In the *Salmonella*/microsomal system, the results indicated that the K-region oxide of DMBA is generated and that it is responsible for binding to DNA. Thus, the activation systems used in bacterial muta-

genesis assays may not faithfully reproduce the activation processes that occur in mammalian tissues. (14 refs)

- 79-0287** Survey of Food Contamination by Benzo(a)pyrene. II. Study of Smoked Products. (Fre) Bories, G. (Laboratoire de recherches sur les additifs alimentaires, I.N.R.A., 180 chemin de Tournefeuille, 31300 Toulouse, France); Tchimbakala, A.; Tchimbakala, E. *Ann Nutr Aliment* 32(4): 811-817; 1978.

Smoked meat, poultry, and fish were analyzed for benzo(a)pyrene residues. The residue levels were $<0.5 \mu\text{g/kg}$ in most samples and $<1 \mu\text{g/kg}$ in all samples except anchovies, in which up to $7 \mu\text{g/kg}$ were found. (12 refs)

- 79-0288** Fibrosarcoma Induced by Administration of Methyl Cholanthere into Post Extraction Sockets of Mandibular Molars in Rats. (Eng) Sela, J. (Div. Oral Pathology, Hebrew University-Hadassah, Sch. Dental Medicine, P.O. Box 1172, Jerusalem, Israel); Harary, D. *Experientia* 35(1): 110-111; 1979.

The effect of 20-methylcholanthere (20-MC) on the tissues involved in the healing of alveolar bone sockets was studied using 55 male and female Hebrew University rats. Following extraction of the mandibular first and second right molars, 10% 20-MC in pellet or crystalline form was introduced into the alveolar bone sockets. In addition, 10% 20-MC in vitepsol H-15 was injected into the surgical site 20 days postsurgery (30 rats) or on 10, 20, and 30 days postsurgery (25 rats). The animals were observed for 9 mo. Fibrosarcomas developed in all surviving 20-MC-treated rats, but osteosarcomas were not induced. These methods are highly recommended for the production of experimental fibrosarcomas, but their use for osteosarcoma induction requires further evaluation. (5 refs.)

- 79-0289** The Aftermath of Feeding of Rats with Canned Fish. (Rus) Neiman, I. M. (Inst. Nutrition, Moscow, USSR); Andrianova, M. M.; Beloshapko, A. A.; Gortalum, G. M.; Kolosnitsina, N. V.; Finogenova, M. A. *Vopr Pitan* (5): 60-67; 1978.

A potential hazard of prolonged consumption of canned fish was evaluated in random-bred rats. Animals were divided into four groups: 86 rats in Group 1 were fed with Atlantic herring in tomato sauce, 76 rats in Group 2 with sprats in tomato sauce, 85 rats in Group 3 with sardines in oil, and 70 rats in Group 4 with a standard diet. The experiment lasted 3 yr. At the end of the experiment, tumors were detected in 14.1% of the rats in Group 1 (10.6% had adenocarcinomas and spindle cell liposarcoma of the mammary gland; 3.5% had benign adenomas and fibroadenomas), 23.3% of the rats in Group 2 (20.5% had adenocarcinomas of the

mammary gland, sarcomas of various locations, or cancer of the thyroid, liver, and skin; 2.7% had benign fibroadenomas of the mammary gland), and in 22% of the rats in group 3 (19.5% had sarcomas and adenocarcinomas of the mammary gland, stomach, liver and lungs; 2.4% had benign adenomas of the mammary gland). The incidence of spontaneous malignant and benign tumors in Group 4 was 6% and 10.4%, respectively. The av latent period of tumor development in Groups 2 and 3 rats was 16 mo and 17 mo, respectively, compared with 20 mo in Group 4. With these findings in mind, the cans were analyzed for the presence of benzo(a)pyrene (BP) and dimethylnitrosamine (DMNA). It was found that Atlantic herring contained $0.41 \mu\text{g/kg}$ of BP and $6.0 \mu\text{g/kg}$ of DMNA, sprats contained $0.08 \mu\text{g/kg}$ and $10.0 \mu\text{g/kg}$, respectively, and sardines contained $1.6 \mu\text{g/kg}$ and $15.0 \mu\text{g/kg}$, respectively. (20 refs)

- 79-0290** Survey of Food Contamination by Benzo(a)pyrene. I. Development of a Universal Method of Determination. Its Application to Complete Meals Prepared by Institutional Catering Services. (Fre) Bories, G. (Laboratoire de recherches sur les additifs alimentaires, I.N.R.A., 180 chemin de Tournefeuille, 31300 Toulouse, France); Tchimbakala, A.; Tchimbakala, E. *Ann Nutr Aliment* 32(4): 801-809; 1978.

A universal spectrofluorometric method was developed for the determination of benzo(a)pyrene in food. The sensitivity of the method was 0.2 ppb at a recovery rate of 85%. The benzo(a)pyrene levels found in complete meals prepared by catering services were $0-1 \mu\text{g/kg}$. (11 refs)

- 79-0291** Rapid Method for the Isolation and Quantitative Analysis of Benzo(a)pyrene in Food. (Ger) Gertz, C. (Chemisches Untersuchungsamt der Stadt Hagen, Pappelstrasse 1, D-5800 Hagen, W. Germany). *Z Lebensm Unters Forsch* 167(4): 233-237; 1978.

The presence of benzo(a)pyrene (BP) in foods can be determined quantitatively by thin-layer chromatography and fluorometry. The BP is first extracted from a petroleum-ether suspension of the sample as a water-soluble caffeine complex, reextracted, and then purified by column chromatography. The recovery rate is 80%. (12 refs)

- 79-0292** Marked Differences in the Skin Tumor-initiating Activities of the Optical Enantiomers of the Diastereomeric Benzo(a)pyrene 7,8-Diol-9,10-epoxides. (Eng) Slaga, T. J. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Bracken, W. J.; Gleason, G.; Levin, W.; Yagi, H.; Jerina, D. M.; Conney, A. H. *Cancer Res* 39(1): 67-71; 1979.

The abilities of the optically pure (+) and (-)-enantiomers of the diastereomeric 7,8-dihydroxy-9,10-epoxy-7,8,9,10-tetrahydrobenzo(a)pyrenes derived from the enantiomeric trans-7,8-dihydrodiols to initiate skin tumors in female Charles River CD-1 mice were determined using a two-stage system of tumorigenesis. (+)-Benzo(a)pyrene (BP) 7 β ,8 α -diol-9 α ,10 α -epoxide 2 (A) effectively initiated tumors in a dose-dependent fashion, whereas (-)-BP 7 β ,8 α -diol-9 β ,10 β -epoxide 1, (-)-BP 7 α ,8 β -diol-9 β ,10 β -epoxide 2 (B), and (+)-BP 7 α ,8 β -diol-9 α ,10 α -epoxide 1 had little or no tumorigenic activity. Compound A had approx 60% of the tumor-initiating activity of BP, compound B approx 2%. Removing the keratinized portion of the skin by pressure-sensitive tape 1 and 2 days before initiation increased the initiating activity of A. In skin tumor-sensitive female Sencar mice, compound A had about 70% of the skin tumor-initiating activity of BP, but the other BP 7,8-diol-9,10-epoxides had little or no tumorigenic activity. Six daily topical applications of 34 nanomoles (nmol) of A resulted in greater tumor-initiating activity than did a single application of 200 nmol, but the activities of BP and B were not increased by fractionated doses. The results indicate that A is the ultimate carcinogenic form of BP 7,8-diol-9,10-epoxide. (30 refs)

79-0293 Tumorigenicity of the Optical Enantiomers of the Diastereomeric Benzo(a)pyrene 7,8-Diol-9,10-epoxides in Newborn Mice: Exceptional Activity of (+)-7 β ,8 α -Dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene. (Eng) Buening, M. K. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ, 07110); Wislocki, P. G.; Levin, W.; Yagi, H.; Thakker, D. R.; Akagi, H.; Koreeda, M.; Jerina, D. M.; Conney, A. H. *Proc Natl Acad Sci USA* 75(11): 5358-5361; 1978.

Benzo(a)pyrene (BP) optical enantiomers were tested for tumorigenicity. The four optically pure isomers of the diastereomeric BP-7,8-diol-9,10 epoxides were tested in newborn Swiss-Webster BLU:Ha(ICR) mice. BP-, (-)-BP-7 β ,8 α -diol-9 β ,10 β -epoxide 1, (+)-BP-7 α ,8 β -diol-9 α ,10 α -epoxide 1, (-)-BP-7 α ,8 β -diol-9 β ,10 β -epoxide 2, and (+)-BP-7 β ,8 α -diol-9 α ,10 α -epoxide 2 were each injected ip into mice in three injections (before 24 hr, at 8 days, and at 15 days of age) to a total dose of 7 nmol or 14 nmol of compound. Upon sacrifice at 34-37 wk, all mice injected with 14 nmol of (+)-BP-7 β ,8 α -diol-9 α ,10 α -epoxide 2 developed pulmonary tumors at a rate of 7.67 tumors/mouse and 71% of those injected with 7 nmol of the compound developed an av of 1.72 tumors/mouse. Only 9%-22% of control mice or mice injected with any dose of the other compounds developed pulmonary tumors (0.09-0.34 tumors/mouse). Because BP is metabolized in vitro with high specificity to (+)-BP-7 β ,8 α -diol-9 α ,10 α -epoxide 2 by liver enzymes and by other target tissues and because it possesses appreciable tumorigenic activity, it is suggested that this compound is a major ultimate carcinogenic metabolite of BP. (39 refs)

79-0294 The Effect of Norharman on the Metabolism of Benzo(a)pyrene by Rat-Liver Microsomes in Vitro in Relation to its Enhancement of the Mutagenicity of Benzo(a)pyrene. (Eng) Fujino, T. (Serology Div., Natl. Cancer Center Res. Inst., 5-1 Tsukiji, Chuo-ku, Tokyo, Japan); Fujiki, H.; Nagao, M.; Yahagi, T.; Seino, Y.; Sugimura, T. *Mutat Res* 58(2/3): 151-158; 1978.

The effect of norharman (NH) on the metabolism of benzo(a)pyrene (BP) by Sprague-Dawley rat liver microsomes was studied. Separation on the metabolites into hydrophilic and hydrophobic fractions showed that NH inhibited the conversion of hydrophobic BP metabolites to hydrophilic ones. Analysis of the hydrophobic metabolites by high-pressure liquid chromatography indicated that NH also inhibited the disappearance of BP itself. However, large amounts of hydrophobic metabolites, such as phenol, quinones and diols, were formed in the presence of NH, and formation of the potent mutagen 7,8-dihydroxyBP was increased tenfold by NH. The increased formation of this compound may be one of the factors responsible for the enhancing effect of NH on the mutagenicity of BP in *Salmonella typhimurium*. (15 refs)

79-0295 The Tumor-producing Effect of Automobile Exhaust Condensate and Fractions Thereof. Part II: Animal Studies. (Eng) Brune, H. (Beratungsfürum für Präventivmedizin und Umwelttoxikologie, Kattrepelsbrücke, 2000 Hamburg 1, W. Germany); Habs, M.; Schmahl, D. *J Environ Pathol and Toxicol* 1(6): 737-745; 1978.

The ability of automobile exhaust condensate and its fractions to produce tumors was studied in mice. In one study, 0.26, 0.79, or 2.37 mg of automobile exhaust condensate or its fractions were applied to the shaved, interscapular region of CFLP mice 3x/wk. The percentage of follicles in which sebaceous glands had disappeared was recorded. In another study, 0.1 ml of each substance was applied 2x/wk for life. The animals were dissected, and both the skin and organs showing abnormalities were examined histologically. In the first study, benzo(a)pyrene, the methanol phase, and cyclohexane phase II were significantly less oncogenic than the total condensate. In the second trial, no significant differences in tumor occurrence could be found between animals treated with fractions containing polycyclic aromatic hydrocarbons (PAH) and those created with the total condensate. (15 refs)

79-0296 The Tumor-producing Effect of Automobile Exhaust Condensate and Fractions Thereof. Part III: Mathematical-Statistical Evaluation of the Test Results. (Eng) Misfeld, J. (Institut für Mathematik, Technische Universität Hannover, Welfengarten 1, 3000 Hannover, W. Germany); Timm, J. *J Environ Pathol and Toxicol* 1(6): 747-771; 1978.

The results of experiments concerning the dose-dependence of carcinogenesis produced by automobile exhaust gas condensate and the condensate fractions responsible for carcinogenesis were evaluated statistically. In particular, the hypothesis that the potency of the entire condensate is mainly due to the fraction containing polycyclic aromatic hydrocarbons (nitromethane phase) was examined. The cyclohexane phase I comprised 34% of the wt of the total condensate, and its relative potency was three times that of the total condensate. The nitromethane phase comprised 17% of the total wt and was approx six times as potent as the total condensate. The remaining part of the cyclohexane phase I (ie, the methanol phase) proved to be responsible for only about 13% of the total potency. Benzo(a)pyrene was responsible for about 10% of the potency of the whole condensate. These results suggest that the nitromethane phase is responsible for a large part of the carcinogenic activity of automobile exhaust condensates. (20 refs)

79-0297 Determination of Chrysene and Benzopyrene in the Atmospheric Environment by Mass Spectrometry. (Jpn) Kuwata, K. (Environmental Pollution Control Center, Osaka, 1-3-62, Nakamichi, Higashinari-ku, Osaka-shi, Japan). *Bunseki Kagaku* 27(10): 650-655; 1978.

A simple, sensitive mass spectrometric method was developed to determine chrysene (CHR) and benzopyrene (BP) in the air. Airborne particulate matter was sampled on a glass fiber filter by a high-volume air sampler for 1 to 24 hr and extracted for 5 hr with 50 ml of cyclohexane in a soxhlet extractor. The extract was reduced to 5 ml by evaporation in a Kuderna-Danish apparatus. Five μ liters of soln was taken into a glass fiber filter sampling probe and 2 μ liters of an internal standard soln containing 100 nanog of benzanthrone (mol wt 234) was added. The sampling probe was dried at room temperature for 2 min and inserted into the ionization chamber of a mass spectrometer. Ion currents of m/e (mass/electric charge) 228, m/e 252, and m/e 234 were measured every 30 sec by the mass spectrometer. Amounts of CHR and BP in the extract were calculated from integrated ion currents of m/e 228 and m/e 252 relative to m/e 234. Working conditions of the mass spectrometer were as follows: 70 electron volts, total emission 80 milliamperes, vacuum $5-6 \times 10^{-7}$ mm Hg, temperature of the ionization chamber 80 C, scan range m/e 226-254. Values of CHR and BP determined by mass spectrometry needed to be corrected by multiplying the value of CHR by 0.953 and the value of BP by 0.693 in the case of ambient air in Osaka because the values were affected by isomers of CHR and BP contained in the airborne particulate matter. Relative standard deviations of measured values of CHR and BP in the range of 0.1 to 50 nanog were 2%-7%, and analysis time of the mass spectrometry was 7 to 8 min/sample. The advantages of the technique are high sensitivity, excellent quantitative accuracy, and simple analytical procedure. (12 refs)

79-0298 Inverse Correlation Between Species Lifespan and Capacity of Cultured Fibroblasts to Convert

Benzo(a)pyrene to Water-soluble Metabolites. (Eng) Moore, C. J. (Dept. Microbiology, Temple Univ. Sch. Medicine, Philadelphia, PA, 19140); Schwartz, A. G. *Exp Cell Res* 116(2): 359-364; 1978.

Diploid lung and skin fibroblasts of eight mammalian species were cultured, and the ability of the fibroblasts to convert benzo(a)pyrene (BP) to water-soluble metabolites was determined. The rate of conversion was dependent on culture density, and it varied widely among different species. There was a very good inverse correlation between species life span and the metabolism of BP to water-soluble metabolites in the cultured fibroblasts of a given species. Peak BP metabolizing activity was in the order hamster > mouse = rat > guinea pig > rabbit > cow > elephant > human ($p < 0.01$), with a 240-fold difference in the activities of the most active species (hamster) and the least active (human). Since these cell systems have also shown a good inverse correlation between species life span and the biological activity of 7,12-dimethylbenz-(a)anthracene, the data suggest that the metabolism of polycyclic hydrocarbon carcinogens is closely related to life span in mammalian species. (22 refs)

79-0299 Retinoids as Well as Tumour Promoters Enhance Deacylation of Cellular Lipids and Prostaglandin Production in MDCK Cells. (Eng) Levine, L. (Dept. Biochemistry, Brandeis Univ., Waltham, MA, 02154); Ohuchi, K. *Nature* 276(5685): 274-275; 1978.

The effects of various retinoids on the deacylation of cellular lipids and production of prostaglandins (PG's) in dog kidney (MDCK) cells were studied. Incubation of MDCK cells with the trimethylmethoxyphenyl (TMMP) analog of retinoic acid (0.1 to 2.0 μ g/ml) resulted in increased production of PGE-2 and PGF-2 α . All other retinoids tested except retinyl palmitate also stimulated PG production to varying degrees. Deacylation of cellular lipids by 3 H-arachidonic acid-labeled cells was stimulated by cis-retinoic acid or TMMP-retinoic acid (2.0 μ g/ml). The level of stimulation was greater with the tumor-promoter 12-O-tetradecanoyl-phorbol-13-acetate (TPA) than with the retinoids. The stimulating effects of TPA and TMMP-retinoic acid were synergistic, whereas those of TPA and cis-retinoic acid were not. The use of vitamin A and some of its analogs to prevent chemical carcinogenesis may, therefore, be premature; they may enhance, not inhibit, tumor formation. (21 refs)

79-0300 Neoplastic Potential in Stratified Epithelial Gradients Following Metaplasia Induced by Nutritional Deficiency of Vitamin A: An Interpretation. (Eng) Van Dyke, J. H. (Dept. Anatomy, Hahnemann Medical Coll., Philadelphia, PA). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International

Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp; 707-725; 1977.

To investigate the fate of basal and suprabasal epithelial cells during tumorigenesis, metaplastic foci (cysts lined by stratified squamous epithelium) were induced in the thyroid and thymus glands of Wistar rats. In rats maintained on vitamin A-deficient diets to induce squamous cell metaplasias, thyroids were mitotically stimulated by the simultaneous dietary estrogen (2 mg/day allylthiourea) and carcinogen (2 mg/day 2-acetylaminofluorene) and thymuses by ip injection of estrogen (estradiol dipropionate 0.25 ml 2 x/wk). Induced metaplastic lesions were similarly stimulated during periods of reacquisition of vitamin A (when cell strata separate during typical epithelial repair), which resulted in neoplasms unique to particular cell-layer gradients. Basal cells from thyroid cysts eventually formed undifferentiated, carcinomatous masses. The cytotreticulum of the thymus produced abnormal thymic corpuscles that ultimately formed multiple cysts. Suprabasal cells from these metaplastic lesions produced "new growths" in both organs: thyroid cystadenomas and thymic spindle cell tumors. It is concluded that nests of suprabasal cells, deeply implanted in a propitious organ environment, are implicated in malignant transformation. When released from intact stratified squamous epithelium (cysts) during repair of metaplasia, these cells, improperly induced, may be a prime source of epithelial, glandular malignancies. (23 refs)

- 79-0301 Analysis of the Aryl Hydrocarbon Hydroxylase Assay.** (Eng) Yang, C. S. (Dept. Biochemistry, New Jersey Medical Sch., Coll. Medicine and Dentistry New Jersey, Newark, NJ, 07103); Strickhart, F. S.; Kicha, L. P. *Biochem Pharmacol* 27(19): 2321-2326; 1978.

The assay method and the properties of aryl hydrocarbon hydroxylase (AHH) were studied with Long-Evans rat liver microsomes. The assay was carried out by two methods: (1) the microsomes (initially at 15-20 C) were preincubated at 37 C, and then benzo[a]pyrene (BP) and NADPH were added to initiate the assay; and (2) BP was added to microsomes at 15-20 C, preincubated at 37 C, and then NADPH was added to initiate the reaction. The AHH activity obtained by method 1 was usually 60%-120% higher than that obtained by method 2. Several lines of study suggested that the microsomes can exist in two states. Binding of BP at temperatures lower than 20 C would limit the microsomes to a low activity state, whereas binding at temperatures above 25 C would enable the microsomes to exist in a high activity state. The molecular basis of these activity states remains to be investigated. The effects of acetone and methanol, both widely used solvents for BP, on AHH were also studied. AHH activities of control and phenobarbital-induced microsomes were higher with acetone as the solvent for BP, compared with methanol. The hydroxylase activity of 3-methylcholanthrene-induced microsomes, however, was slightly higher with methanol. (29 refs)

- 79-0302 Differences Between the Hydroperoxide-dependent and NADPH-Dependent Microsomal Aryl Hydrocarbon Hydroxylase Activities.** (Eng) Yang, C. S. (Coll. Medicine and Dentistry of New Jersey, Newark, NJ, 07103); Strickhart, F. S. *Biochem Pharmacol* 27(19): 2376-2378; 1978.

The hydroperoxide-dependent and NADPH-dependent microsomal aryl hydrocarbon hydroxylase (AHH) systems were compared with regard to the relative catalytic activities of cytochrome P-450- and cytochrome P-448-containing microsomes they contain, as well as the actions on them of specific inhibitors of the mono-oxygenase system. The results indicated that there is no parallelism between the NADPH- and hydroperoxide-dependent systems with regard to the AHH activities of the different types of microsomes. (16 refs)

- 79-0303 Effects of Dietary Cyclopropene Fatty Acids on the Mixed Function Oxidase System of the Rainbow Trout (*Salmo gairdneri*).** (Eng) Eisele, T. A. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR, 97331); Nixon, J. E.; Pawlowski, N. E.; Sinnhuber, R. O. *J Environ Pathol Toxicol* 1(6): 773-778; 1978.

Dietary cyclopropene fatty acids (CPFA) in rainbow trout (*Salmo gairdneri*) decreased cytochrome P-450 and b₅ content and NADPH-cytochrome c reductase activity 67.8%, 22.0%, and 38.4%, respectively, compared with control-fed trout after 22 days. Dietary CPFA induced benzo(a)pyrene aryl hydrocarbon hydroxylase 37.5% over controls over the same time period. Microsomal protein levels were consistently lower in CPFA-fed trout throughout the experiment (74 days). The data suggest a possible mechanism by which dietary CPFA act as cocarcinogens. (25 refs)

- 79-0304 Epoxide Hydratase and Benzo(a)pyrene Monooxygenase Activities in Liver, Kidney and Lung after Treatment of Rats with Epoxides of Widely Varying Structures.** (Eng) Schmassmann, H. (Inst. Pharmacology, Univ., Obere Zahlbacher Strasse 67, D-6500 Mainz, W. Germany); Sparrow, A.; Platt, K.; Oesch, F. *Biochem Pharmacol* 27(18): 2237-2245; 1978.

The effects of various epoxides on epoxide hydratase and benzo(a)pyrene monooxygenase activities were investigated in the rat liver, kidney, and lung in an effort to identify a selective inducer of epoxide hydratase. With respect to five measured monooxygenase parameters, trans-stilbene oxide (TSO) was found to selectively induce hepatic epoxide hydratase activity. (53 refs)

- 79-0305 Thin-Layer Chromatographic-Fluorometric Determination of Diethylstilbestrol in the Urine**

and Feces of Calves Being Fattened for Market. (Ger) Vogt, K. (Institut für Physiologie, Süddeutsche Versuchs- und Forschungsanstalt für Milchwirtschaft, 805 Freising-Weihenstephan, W. Germany). *Arch Lebensmittelhyg* 29(5): 178-181; 1978.

Diethylstilbestrol can be determined in bovine fecal and urine samples at a sensitivity of 10 nanograms/ml by thin-layer chromatography and fluorometry following treatment of the extract with 5-dimethylaminonaphthalenesulfonic acid. The use of diethylstilbestrol to fatten calves is illegal in West Germany. (15 refs)

79-0306 Metabolism of Diethylstilbestrol: Identification of a Catechol Derived from Dienestrol. (Eng) Weidenfeld, J. (Hadassah Medical Sch., Hebrew Univ., Jerusalem, Israel); Carter, P.; Reinhold, V. N.; Tanner, S. B.; Engel, L. L. *Biomed Mass Spectrom* 5(10): 587-590; 1978.

A catechol metabolite of diethylstilbestrol (DES) was formed after incubation of DES with mushroom tyrosinase or rat liver microsomes in the presence of oxygen and NADPH. Both catechols were further oxidized with periodate to form o-quinones and then condensed with o-phenylenediamine to form stable phenazines. The gas chromatographic retention times and mass spectrometric fragmentation patterns of these phenazines were identical to that of the phenazine prepared by oxidation of DES with potassium nitrosodisulfonate (Fremy's salt) and treatment of the resulting o-quinone with o-phenylenediamine. The high- and low-resolution mass spectra of the phenazine were consistent with its derivation from a catechol having two fewer hydrogens than DES. This is the first direct demonstration of the formation of a catechol metabolite of DES in vitro by both a mammalian and a plant enzyme system. (16 refs)

79-0307 Morphological and Functional Consequences of Prenatal Exposure to Diethylstilbestrol in the Rat. (Eng) Boylan, E. S. (Dept. Biology, Queens Coll. City Univ. New York, Flushing, NY, 11367). *Biol Reprod* 19(4): 854-863; 1978.

Pregnant Sprague-Dawley rats were treated with diethylstilbestrol (DES) during the second or third trimester (Tr) of gestation to determine the effects of exposure to DES in utero on the offspring. Total DES doses of 12,000, 1,200, 120, 60, 12, or 1.2 μ g were administered sc in two or three injections during Tr 2 or 3. A total dose of 120 μ g in Tr 3 allowed 62% of animals to deliver normally, whereas doses between 12,000 and 12 μ g in Tr 2 resulted in fetal retention or abortion in the majority of animals. The highest dose of DES resulted in prominent nipple development in both males and females in utero, and microscopic examination showed that the epithelial hood was lacking in nipples of female retained fetuses and neonates exposed to ≥ 120 μ g DES in either Tr 2 or 3.

Females exposed to 1.2 μ g or 120 μ g DES during Tr 3 had precocious opening of the vagina, and 8/15 of the animals exposed to 120 μ g DES were barren when mating was attempted. Of seven pregnant females that received 120 μ g DES, four gave birth to live pups, but the pups of only two mothers survived to weaning. Other abnormalities, such as incomplete fusion of the urethra, enlarged ovaries (including cysts or solid masses), and distended uterine horns and vaginas, were seen in 7/32 females exposed in utero to 120 μ g DES, but male offspring appeared unaffected by maternal DES treatment. This report confirms that DES is transported transplacentally in the rat and has effects on a variety of fetal tissues. (14 refs)

79-0308 Absorption and Glucuronylation of Diethylstilbestrol by the Rat Small Intestine. (Eng) Lasker, J. (Chemical Industry Inst. Toxicology, PO Box 12137, Research Triangle Park, NC, 27709); Rickert, D. E. *Xenobiotica* 8(11): 665-672; 1978.

The absorption and glucuronylation of (14 C)diethylstilbestrol (DES) were studied in situ in segments of male Sprague-Dawley rat small intestine with intact arterial supply and complete collection of venous blood. A 0.5 ml aliquot of 0.1, 1.0, 2.0, or 5.0 mM DES in isotonic saline-20% ethanol plus a tracer of 14 C-DES were instilled into the intestinal lumen, and venous blood collected for six 10-min periods. All methanol-soluble radioactivity in the intestinal venous blood, the luminal contents, and the intestinal tissue co-chromatographed with authentic DES or authentic diethylstilbestrol glucuronide. There was no difference between DES glucuronide formation in intestinal segments near the pyloric sphincter and in segments located near the ileocecal junction. The appearance of DES and DES glucuronide in the venous blood of aborally-located segments was dose-dependent from 0.1 to 5 mM, but in orally-located segments, an increase in DES concentration from 2 to 5 mM produced no increase in the content of DES or its glucuronide. DES and DES glucuronide content in the intestinal wall increased with increasing DES concentration in both regions of the intestine. In the lumen, however, DES-related materials increased with dose in oral segments, but there was no increase in the aboral segments when DES concentration was raised from 2 to 5 mM. Appearance of DES and DES glucuronide in the venous blood was independent of blood flow. The results suggest that intestinal glucuronylation during absorption may be significant over a wide range of concentrations in all regions of the intestine. (23 refs)

79-0309 Liver Tumours Associated with Oral Contraceptives. (Eng) Britton, W. J. (Royal Prince Alfred Hosp., Camperdown, NSW 2050, Sydney, Australia); Gallagher, N. D.; Little, J. M. *Med J Aust* 2(6): 223-227; 1978.

The case reports of five women (ages 21-30 yr) who were users of oral contraceptive agents (OCA) and who developed liver tumors are presented. All patients had been using OCA for periods ranging from 0.5 to 10 yr. One patient was originally investigated because of hepatomegaly, two noticed an abdominal mass themselves, one first complained of dull abdominal pain, and one suffered obstructive jaundice. The masses were successfully removed in three patients, and all were diagnosed as adenomas. The fourth patient, who also had an adenoma, suffered a massive intraabdominal hemorrhage during an attempted percutaneous liver biopsy, and eventually died from complications. The jaundiced patient had a well-differentiated primary hepatocellular carcinoma that invaded the biliary tree; she eventually died of liver failure. The adenomas were composed of uniform to slightly atypical hepatocytes arranged in cords or pseudoacini around secreted and retained bile. Bile ducts were only occasionally identified, and the usual lobular architecture was absent. Cell tumors were highly vascular, and differentiation of the vascular supply permits a planned surgical approach to the lesion. No one particular type of OCA was implicated as being causative. It is suggested that the diagnosis of liver tumor be considered in any OCA users presenting with obscure abdominal pain, hepatomegaly, an abdominal mass, or surgical emergency of hemoperitoneum. (30 refs)

- 79-0310 Liver Tumors and Oral Contraceptives: Pathology and Pathogenesis.** (Eng) Gindhart, T. D. (Dept. Pathology, Univ. California, San Francisco, CA, 94143). *Ann Clin Lab Sci* 8(6): 443-446; 1978.

Two case histories are reported to illustrate the different pathological features of hepatocellular adenoma (HCA), which is associated with oral contraceptive (OC) use, and focal nodular hyperplasia (FNH), which appears to be only coincidentally associated but with a particular hemorrhagic tendency. A 33-yr-old woman with a 7-yr history of OC use presented with right upper abdominal pain of 5 mo duration. During the 30 mo before presentation, she had taken an OC containing 2 mg chlormadinone acetate and 80 μ mestranol. Serum alkaline phosphatase was slightly elevated, but other serum indicators of liver condition were normal. Liver scan showed two HCA's, a 9-cm vascular mass and a 6-cm avascular mass. Microscopically, large hepatocytes arranged in haphazard plates accompanied by Kupffer cells were evident, but portal triads and bile duct proliferation were absent. The latter feature distinguishes FNH from HCA. Fibrosis was only present in a capsule surrounding the tumor. Case 2 was a 28-yr-old woman who had taken OC's intermittently for 9 yr until 10 mo prior to death from cervical carcinoma. A 1.5-cm-diameter, well-demarcated lesion of FCN was an incidental finding on autopsy. Microscopically, the lesion resembled regeneration nodules of cirrhosis. Enlarged hepatocytes arranged in plates and fibrous septa with bile duct proliferation were evident. Right upper quadrant pain with abdominal hemorrhage is the most common clinical presentation of HCA, a condi-

tion for which mestranol-containing preparations appear particularly hazardous. (22 refs)

- 79-0311 Combined Oral Contraceptives and Cancer of the Uterine Cervix.** (Nor) Nesheim, B. I. (No affiliation given). *Tidsskr Nor Laegeforen* 98(29): 1422-1423; 1978.

Two surveys covering 6,000 and 14,000 women, respectively, showed a positive correlation between the use of combined oral contraceptives and cervical cancer. The cancer risk increased with duration of use. (5 refs)

- 79-0312 Oral Contraceptives and Endometrial Cancer.** (Eng) Silverberg, S. G. (Colorado Regional Cancer Center, Univ. Colorado Sch. Medicine, Denver, CO, 80262). In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp; 73-87; 1978.

Of 30 endometrial tumors included in a registry of tumors developing in women < 40 yr taking oral contraceptives, 22 were Grade I adenocarcinomas, adenocanthomas, or secretory carcinomas. The only histologic difference between the registry tumors and those in 25 controls who had not received oral contraceptives was in the frequency of pure clear cell or secretory carcinomas or carcinomas with a focal secretory pattern (14/29 registry cases vs 2/25 controls). There was only one tumor-related death in the registry group, and myometrial invasion was observed in only 2/18 patients who underwent hysterectomy without prior radiation therapy. Two-thirds of the patients had taken sequential agents (eg, Oracon), and nine had taken combined agents (eg, estrogen and progestagen) that were prescribed in seven cases for vaginal bleeding or polycystic disease consistent with the Stein-Leventhal syndrome. The results indicate that different types of estrogens can have the same end effect on the endometrium. (32 refs)

- 79-0313 Estrogen Receptor in the Mammalian Liver: Effect of Metabolism on the Amount and Identity of Receptor-bound Estrogen.** (Eng) Weinberger, M. J. (Dept. Molecular Medicine, Mayo Clinic, Rochester, MN, 55901); Aten, R. F.; Eisenfeld, A. J. *Biochem Pharmacol* 27(20): 2469-2474; 1978.

Estrogen-liver interactions were studied by incubating liver slices from ovariectomized CD rats with 2,4,6,7-³H-estradiol [³H-E₂: specific activity 100 Ci/millimole (mmol), 200 disintegrations/min/femtomole (dpm/fmol)] or with 6,7-³H-E₂ (47 Ci/mmol, 100 dpm/fmol) in phosphate buffer. Macromolecule-bound radioactivity in purified cytosol and nu-

clear fractions was determined by gel filtration on Biogel P-10 columns. Max binding in both fractions occurred at a E_2 concentration of 5×10^{-8} M. Of the $^3H-E_2$ originally present in the medium, 97% was metabolized in < 15 min after incubation of the liver slices at 25 C. When testosterone (5×10^{-6} M) was added to medium containing submax $^3H-E_2$ concentrations, increased cytosol binding was observed after 5, 15, and 30 min, increased nuclear binding after 30 and 60 min. Hexobarbital (1×10^{-3} M) also increased nuclear radioactivity after a 1-hr incubation period. In the nuclear fraction, E_2 represented 52% and 2-hydroxyestradiol 36% of the radioactivity bound after the liver slices were incubated at 37 C for 1 hr. Diethylstilbestrol reduced the binding of these major metabolites (from approx 21,000 to 5,000 dpm/g liver), which suggested a specific interaction between the nuclear receptor and the two estrogens. Thus, the risk of liver tumors from oral contraceptives might be minimized by the use of estrogens that are metabolized preferentially to inactive derivatives in the liver. (16 refs)

- 79-0314 Treatment of Tall Girls with Estrogen.** (Eng) Crawford, J. D. (Children's Service, Massachusetts General Hosp., Boston, MA, 02114). *Pediatrics* 62(6, part 2, Suppl): 1189-1195; 1978.

The effects of using estrogens to curb the statural growth of tall girls are reviewed. One series of 100 girls was treated between 1955 and 1971 with 5 mg/day diethylstilbestrol (DES) and 5 mg/day norethindrone for the first 5 days of each mo. In another series of 26 girls, treated during 1968-1976, the DES was replaced by 0.25 mg/day ethinyl estradiol. Ovarian tumors were not encountered in these two series. One girl with a benign serous cystadenoma of the ovary that became symptomatic during treatment with 10 mg/day conjugated estrogens was found upon referral. Another girl was referred for increasing asymmetry of the breasts after 4 mo treatment with 5 mg/day DES. A large fibroadenoma mole was removed that probably existed before the start of treatment. In one patient of the second series, a nodule detected after 15 mo treatment with ethinyl estradiol proved to be a benign intraductal papilloma. (32 refs)

- 79-0315 Menopausal Therapy and Endometrial Pathology (Letter to Editor).** (Eng) Studd, J. (Dulwich Hosp., London SE22, England); Thom, M.; White, P. J. *Br Med J* 2(6148): 1369; 1978.

The dose schedule and treatment of 34 postmenopausal patients with endometrial hyperplasia who received hormone replacement therapy are discussed. Only 7 of the 29 patients with cystic glandular hyperplasia were receiving progestogen. Twelve of the 16 cases occurring with estrogen implants were associated with failure to take the prescribed norethisterone each month. The endometrial pathology was reversible in most cases with two courses of norethisterone. (no refs)

- 79-0316 Postmenopausal Estrogens and Endometrial Cancer: Clinicopathologic Correlations.** (Eng) Miller, A. (Dept. Pathology, Rush Medical Sch., Chicago, IL, 60612); Mullen, D.; Faraci, J. A.; Makowski, E. L.; Silverberg, S. G. In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp.; 35-42; 1978.

A preliminary study of the relationship between postmenopausal estrogen use and endometrial carcinoma in 114 patients is presented. The prevalence of diabetes, hypertension, and obesity in the 39 postmenopausal cancer patients who had received estrogen was significantly lower ($p < 0.001$) than in 75 postmenopausal cancer patients who had received no estrogen. There was less of a tendency to nulliparity or low parity among the estrogen users. The time between the last normal menstrual period and the diagnosis of carcinoma were similar among users and nonusers (13.6 and 12.0 yr, respectively), while the users had a shorter duration of symptoms before diagnosis (4.6 mo) than did the nonusers (7.8 mo). However, there was little evidence of differences in extent of disease between the two groups. Analysis of the histologic type and grade of the tumors seen in the two groups revealed one major difference: mixed adenosquamous carcinoma comprised 28% of cases in nonusers versus only 15% of cases in estrogen users. Vascular invasion was more common in hysterectomy specimens of the nonusers (10/54 cases) than in those of the users (2/37). Clear and ciliated cells occurred more frequently in estrogen-related tumors. The incidence of associated endometrial hyperplasia in either the curettage or hysterectomy specimen showed no significant difference between users and nonusers. Only 25% of users and 20% of nonusers failed to show hyperplasia in at least one slide. (23 refs)

- 79-0317 Differential Biological Activity of Estradiol Metabolites.** (Eng) Fishman, J. (Rockefeller Univ., 1230 York Ave., New York, NY, 10021); Martucci, C. *Pediatrics* 62(6, part 2, Suppl): 1128-1133; 1978.

The role of estradiol metabolism in the expression of the biological activity of the female sex hormone is reviewed. Estrone and estriol were found to be equivalent to estradiol as uterotrophic agents, but no uterotrophic activity was demonstrated with 2-hydroxyestrone. There is now considerable suggestive evidence that the spectrum of estrogenic action can be resolved by specific substances. (35 refs)

- 79-0318 Estrogen Use--Risk of Endometrial Carcinoma.** (Eng) Hoogerland, D. L. (Dept. Obstetrics-Gynecology, David Grant USAF Medical Center, Travis AFB, CA, 94535); Buchler, D. A.; Crowley, J. J.; Carr, W. F. *Gynecol Oncol* 6(5): 451-458; 1978.

A retrospective analysis was carried out to determine the rate of prior usage of exogenous estrogens in all endometrial adenocarcinoma patients treated in a Wisconsin hospital from 1960 to 1974. Rates for matched controls with a different gynecologic malignancy were also determined. Of the total 1,174 patients, 108/587 of the cases and 54/587 of the controls had estrogen exposure, yielding a relative risk of 2.2. The relative risk increased with duration of exposure from 1.2 for 1-6 mo usage to 6.7 for > 10 yr usage. Most of the endometrial lesions in exposed and unexposed patients were pure adenocarcinomas, and the bulk in both groups were low grade-early stage. Although there was a statistically significant increase in exposure rate from 1970 to 1974, the relative risk did not change significantly from earlier years. Hypertension, diabetes mellitus, and obesity were significant risk factors by themselves, but estrogen use did not appear to increase the risk in patients with these conditions. Estrogen users without these predisposing factors had a nonsignificantly higher relative risk (3.2) than those who did have them (2.0). An association between exogenous estrogens and endometrial carcinoma must be considered. (14 refs)

79-0319 Alternative Analytic Methods for Case-Control Studies of Estrogens and Endometrial Cancer. (Eng) Horwitz, R. I. (Robert Wood Johnson Clinical Scholar Program, Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT, 05610); Feinstein, A. R. *N Engl J Med* 299(20): 1089-1094; 1978.

In a case-control study of estrogens and endometrial cancer, alternative sampling methods were used to eliminate the detection bias that arises from the increased diagnostic attention received by women with uterine bleeding after estrogen exposure. Two separate case-control studies were performed at the same institution. In Study 1, cases and controls were selected by the conventional procedure; Study 2, cases and controls were allowed to emerge from the results found in a group of women referred for the same intraendometrial diagnostic procedure. The patients source for Study 1 was 561 patients with gynecologic cancer, 119 of whom had endometrial cancer (first case group). In Study 2, there were 6,869 women who underwent dilatation and curettage or hysterectomy because of uterine bleeding, 149 of whom had endometrial cancer (second case group). Each endometrial cancer patient in both groups had an age- and race-matched control. The odds ratio in Group 1 was 11.98, that in Group 2 was 1.7. A

methodologic analysis demonstrated detection bias arising from the pattern of hospital referral and showed the way in which the bias is neglected or increased by conventional sampling procedures but reduced by the alternative procedure. The magnitude of the association between estrogens and endometrial cancer has been greatly overestimated because of detection bias; when an appropriate compensation for the bias is introduced, the odds ratio approaches a value much closer to 1. (14 refs)

PHYSICAL CARCINOGENESIS

- 79-0320 Estimation of Inhalation Doses from Airborne Releases Using Gross Monitors.** (Eng) Goldstein, N. P. (Westinghouse R & D Center, Pittsburgh, PA, 15235). *Health Phys* 35(5): 675-683; 1978.

The problem of determining inhalation doses from various effluent streams of nuclear power plants by using the results from gross monitoring of airborne releases is considered. This type of monitor will accurately indicate dose, regardless of the isotopic makeup of a release, if its response to each isotope is proportional to the dose factor of that isotope. Gross beta and gross gamma counters were compared with respect to this criterion. Beta counters provide a better estimate of the dose than did gamma counters, as determined by using published power-plant emission data. A variety of other mathematical response functions were also considered but their dose-estimating capabilities were not better than the straight beta response. Although there is a basic limitation in the dose estimation capabilities of gross counters, it is concluded that reasonably accurate estimates of av dose can be achieved using properly selected gross counters and that significant errors can result with improper ones. (8 refs)

- 79-0321 A Perspective on the Radiation Protection Problem and Risk Analysis for the Nuclear Era.** (Eng) Vohra, K. G. (Dept. Atomic Energy, Bhabha Atomic Res. Centre, Bombay, India). *Int Atomic Energy Agency Bull* 20(5): 35-43; 1978.

A comparative analysis of the health risks resulting from exposure to ionizing radiation and to toxic chemical substances released from fossil fuel-burning facilities is presented to assess the relative risks of generating power by nuclear and fuel-burning methods. Quantitative risk from ionizing radiation can be extrapolated from existing data, assuming low dosage linearity and absence of a threshold. This analysis generates a risk value of 200 cancer deaths/million population/rem/yr for individuals continually exposed to 1 rem/yr over a lifetime. Natural radiation from all sources is calculated to be 100 millirem (mrem)/yr, which (based on the given risk calculation) leads to 1000 to 2000 deaths/million/yr due to spontaneous radiation. For comparison, the exposure from a nuclear power station is approx 5 mrem/yr, resulting in one excess cancer death/million/yr; the exposure from diagnostic radiation is 20-100 mrem/yr, generating an additional 10 deaths/million/yr. Lung cancer incidence has risen steadily for 20 yr, and a regression analysis shows that an increment of approx 152 lung cancer deaths/million/yr/ton of coal consumed/person has been contributed in England and Wales by air pollution. The specific coal combustion pollutant benzo(a)pyrene (BP), at a dose equivalent of 1 ng/meter³ (m³)

(actual concentrations in world cities are 1-4 ng/m³) results in excess lung cancer deaths (48/million/yr). Although BP is only one carcinogen present in combusted fuels and lung cancer is only one possible resulting disease, this last risk value serves as a quantitative proof of the relative hazards of the two power generating processes. It is concluded that nuclear power plants are safer than combustion-driven plants for generating energy. (14 refs)

- 79-0322 Transformation of Mouse C3H/10T1/2 Cells by Single and Fractionated Doses of X-Rays and Fission-Spectrum Neutrons.** (Eng) Han, A. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL, 60439); Elkind, M. M. *Cancer Res* 39(1): 123-130; 1979.

A mouse embryo-derived cell line, C3H/10T1/2, was used to measure the frequency of in vitro neoplastic transformation induced by 50-kilovolt peak x-rays and by fission-spectrum neutrons from the JANUS reactor at the Argonne National Laboratory. The transformation frequency after single x-ray doses rose exponentially, reaching a plateau at about 3×10^{-3} transformant/survivor. The induction curve following single neutron doses, although qualitatively similar, initially rose more steeply and then leveled off at a max of about 6×10^{-3} transformant/survivor. For both radiations, the transformation frequency varied with changes in the number of viable cells per dish, showing about a 10-fold decrease in transformation frequency when the number of viable cells per 90-mm dish was increased from about 300 to about 1,000. Fractionation of the total x-ray dose of 700 rads resulted in an approx six-fold increase in survival and a reduction in transformation frequency over a 16-hr interval. Fractionation of the total neutron dose of 378 rads had no effect on cell survival, and transformation frequency declined by a factor of only about 1.7 at most over a 24-hr period. Cells derived from transformed foci formed fibrosarcomas when injected into appropriately treated mice. (44 refs)

- 79-0323 Some Major Statistical Comments on "Radiation Exposures of Hanford Workers Dying from Cancer and Other Causes" (Letter to Editor).** (Eng) Gertz, S. M. (Porter-Gertz Consultants, Inc., Radiological Protection and Environmental Services, 76 Rittenhouse Place, Ardmore, PA, 19003). *Health Phys* 35(5): 723-724; 1978.

A previous conclusion that low-level radiation exposure caused cancer in Hanford workers was not supported by the data or analyses presented. Because an improper control group (cancer deaths of white US men in 1960) was used, the

study failed to prove an increase in cancer deaths in the examined population. It also failed to show that those dying from cancer received a greater absorbed dose than those who died from other causes, it failed to show an increase of cancer deaths with increased absorbed doses, and it used an inappropriate statistical procedure to determine those cancers with radiation associations. 79-0328 Influence of Radiation Exposure Rate on Somatic Mutation Frequency and Loss of Reproductive Integrity in *Tradescantia* Stamen Hairs.

(Eng) Ichikawa, S. (Biology Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Nauman, C. H.; Sparrow, A. H.; Takahashi, C. S. *Mutat Res* 52(2): 171-180; 1978.

The influence of gamma irradiation on somatic mutation frequency and the loss of reproductive integrity in *Tradescantia* stamen hair cells was examined. *Tradescantia* clone 02 was irradiated with gamma-rays at 29.3 R/min for 1.5-12 min (high exposure rate (HER)) or 0.026-0.52 R/min for 16 hr (low exposure rate (LER)). *T. blossfeldiana* was similarly irradiated with 256 R/min for 1.5-12 min or 0.52-41.7 R/min for 16 hr. Somatic mutations were scored as pink cells in otherwise blue terminal hairs, and loss of reproductive integ-

rity was scored as stunting of the stamen hairs. Somatic mutations were first noted in clone 02 on day 6 after HER and day 7 after LER; the frequency of mutational events peaked on days 8-12. At LER, the slope of the mutation-response curve was 0.98, giving a mutation frequency of 9.2×10^{-4} pink mutations/hair/R. The HER mutation-response slope was 1.24, increasing from 1.2×10^{-3} pink mutations/hair R at lowest exposure (38R) to 1.6×10^{-3} pink mutations/hair at highest exposure (114R). Maximum frequencies of stunted hairs were observed at 10-15 days in clone 02 and at 13-25 days in *T. blossfeldiana*. Maximum production was generally observed later at higher exposures and exposure rates. The D_0 values (doses at which 37% of the treated cells survived) for clone 02 were 154 R and 270 R for HER and LER, respectively, and the analogous figures for *T. blossfeldiana* were 720 R and 1880 R. These D_0 's are within the range normally determined for mammalian cells, indicating that these systems may be comparable in this regard. (44 refs)

79-0329 Mutation in *Escherichia coli* During Photodynamic Inactivation and Subsequent Holding in Buffer.

(Eng) Basu, S. (Dept. Physics, Calcutta Univ. Coll. Science, 92 Acharya Prafulla Chandra Road, Calcutta 700 009, India); Bagchi, B. *FEBS Lett* 96(1): 26-30; 1978.

The level of mutation induced in *Escherichia coli* B/r cells during dye-sensitized irradiation and subsequent holding of the cells in buffer at 37 C in the dark was determined. The cells were sensitized with acriflavine (15 μ g/ml) in the dark for 45 min and then irradiated with visible light flashes of 9.5×10^3 joules/m² or with low doses of 253.7-nanometer UV light. Mutagenicity was scored by counting the number of histidine revertants after the cells were plated on partially enriched minimal agar. A high level of mutation occurred both during dye-sensitized irradiation and subsequent holding in buffer, indicating that most of the damage in the photodynamically treated cells was incapable of being repaired by an error-free excision repair pathway. The slope of the log of the mutation frequency vs log of the radiation dose (both visible and UV) had a slope near unity, indicating a linear dependence. Reversion frequency also increased as a function of holding time. The effect of visible light alone on low-UV mutagenesis was almost negligible compared with that of dye + visible light. The high level of mutation induced by low-dose UV may be due to a loss of immunity of the newly synthesized DNA to error-prone repair. (30 refs)

79-0330 X- or γ -Ray Leukemogenesis in Humans.

(Eng) Rosen, P. (Dept. Physics and Astronomy, Univ. Massachusetts, Amherst, MA, 01003). *J Theor Biol* 75(4): 603-606; 1978.

A proposed model for ionizing radiation-induced leukemogenesis in humans is an extension of an earlier model for UV-induced carcinogenesis, in which a mutation occurs in

the operator region of a gene controlling the synthesis of divisional proteins (proteins that are signals for mitosis initiation). For γ -rays, thymine base damage is assumed to be the major damage causing neoplastic transformation. The model was used to calculate the frequencies of myeloid leukemia (ML). It was assumed that there exists a radiation target on the genome that, when struck, initiates events leading to ML and that there exists a repressible gene for WBC maturation. Thus, the following scenario can be assumed: two repressors account for a sequential repression of gene expression. Inactivation of the first repressor (by x-ray damage to its corresponding operator region) permits synthesis of the second, which will repress the expression of the WBC maturation gene. Assumption is also made of a dose-squared relationship based on a two-hit process in which one hit damages a gene specifying a repair process and the second causes a leukemogenic mutation. A mutation frequency per locus per rad of approx 2×10^{-7} was used in an equation that estimates the probability of leukemogenesis per cell. This probability was calculated for four different doses, and the data were compared with previous data. At 200 rads, the probability is 10^{-4} /cell. (22 refs)

79-0338 Role of Testosterone in the Development of Radiation-induced Prostate Carcinoma in Rats. (Eng) Takizawa, S. (Dept. Cancer Res., Res. Inst. Nuclear Medicine and Biology, Hiroshima 734, Japan); Hirose, F. *Gann* 69(5): 723-725; 1978.

The effect of testosterone (TS) on the development of x-ray-induced prostate cancer was studied in male Sprague-Dawley rats. Five-week-old rats were castrated and treated with TS (monthly im injections of 2.5 mg for 2 mo, then 5.0 mg) for their life span. At 6 wk of age, they were irradiated in the pelvic region with a total of 5,000 rads of x-rays delivered in five doses at intervals of 2 or 3 days. Other groups of rats were castrated and irradiated locally, irradiated locally, or untreated. Prostate cancer developed only in the hormone-replaced rats, and the incidence was 4/12 at 7-11 mo after irradiation. There was 1 moderately differentiated adenocarcinoma, 1 undifferentiated carcinoma, and 2 mucus-secreting adenocarcinomas. Metaplastic and atypical growth of the glandular epithelium was found in the ventral and dorsal lobes in both irradiated, intact (3 cases) and hormone-replaced rats (6 cases). These lesions might be a distorted regeneration of glandular epithelia, and they may lead to a neoplasm. The absence of prostate tumors in the irradiated, intact rats was unexpected. Apparently, Sprague-Dawley rats are resistant to the tumorigenic action of x-rays in the prostate gland (compared with Wistar rats). It is concluded that TS acted as a promoter for the development of prostate cancer and precancerous lesions. It is not known whether TS per se is a carcinogen. (7 refs)

79-0339 The Ratio of Cytochromes in Radiation-induced Leukemia Cells of Mice. (Eng) Irie, S. (Radi-

tion Center Osaka Prefecture, Osaka, Japan); Okumoto, M.; Takamori, Y. *Radiat Res* 76(2): 339-348; 1978.

Cytochrome aa₃, b, c₁, and c levels were compared in normal thymocytes from NIH Swiss mice (NT), a spontaneous thymic lymphoma of AKR mice (STL), a radiation-induced thymic lymphoma (RTL) in NIH Swiss mice, and three different lines of transplantable ascites thymic lymphoma cells (TL-69, TL-75, and TL-76). Cytochrome content was determined from difference spectra between the anaerobic and aerobic states at room temperature and at the temperature of liquid nitrogen. The concentration of cytochrome aa₃ was 77 picomoles (pmol)/mg protein in NT, 80 in STL, and 97 in RTL, but it decreased to 70, 58, and 61 pmol/ng protein in TL-76, TL-75, and TL-69 cells, respectively. The cytochrome c + c₁ concentration was similar in STL, TL-75, and NT (94-106 pmol/ng protein), but it increased to 129 pmol/ng in RTL and 145 pmol/ng in TL-69 cells. The cytochrome b level increased to 107 and 105 pmol/ng in STL and RTL, but the TL cell levels were similar to that of NT (74 pmol/ng). The c₁/aa₃ ratios in all tumor cells and the c + c₁/aa₃ ratios in the two primary lymphomas were comparable to those in NT, but the c + c₁/aa₃ ratio in the TL cells rose gradually with successive passage in vivo. Wt gain and survival studies in RF and NIH mice inoculated ip with 1 x 10⁷ TL-69 or TL-75 cells indicated that TL-69 cells grew more rapidly in the peritoneal cavity of mice and was the more virulent tumor cell line. 79-0340 The Induction of Dicentric Chromosome Aberrations in Human Lymphocytes By Unequal Split Doses of X-Radiation. (Eng) Purrott, R. J. (Natl. Radiological Protection Board, Harwell, Didcot, Oxfordshire, England); Reeder, E. J. *Mutat Res* 52(2): 291-293; 1978.

Dicentric aberration yields induced in human lymphocytes by 250-kilovolt peak x-rays given in single exposures or in two unequal dose fractions were studied. Whole-blood samples from a healthy donor were irradiated with two pairs of unequal doses (100 + 300 or 300 + 100, and 100 + 500 or 500 + 100 rads), with each fraction being delivered 24 hr apart, or with unsplit control doses of 100, 200, 300, 400, 500, and 600 rads. The minicultures were incubated with colcemid, and complete metaphases were analyzed for dicentric chromosomes. The number of dicentrics per cell (d/c) was 0.89 for 100 + 300 rads, 0.81 for 300 + 100 rads, 1.88 for 100 + 500 rads, and 1.90 for 500 + 100 rads. There was no significant difference between the two dicentric yields for each total dose, indicating that the size of the initial fraction does not influence overall aberration yield. In addition, the dicentric yields for all fractionated exposures were lower than their unsplit value of 1.02 (400 rads) and 2.11 (600 rads) d/c. For the 100/300 pairs, the observed yields agreed closely with the predicted additive value of 0.84 d/c; the 100/500-rad yields were closer to the additive value (1.78 d/c) than the unsplit value. Therefore, the difference between observed and expected baselines in dicentric yield found in

a previous dose-fractionation study cannot be explained on the basis of radiation affecting break-initiation or repair processes. (4 refs)

79-0341 A Somatic Dose Index for Diagnostic Radiology. (Eng) Laws, P. W. (Dickinson Coll., Carlisle, PA, 17013); Rosenstein, M. *Health Phys* 35(5): 629-642; 1978.

A somatic dose index is illustrated for an adult patient undergoing typical diagnostic radiology. The index was formulated by applying the relative sensitivity of the human body to each of the most important somatic effects and using the absorbed dose in the affected organs. This quantity was then used to convey a cumulative somatic impact and was computed for common radiographic views in diagnostic radiology as a function of beam quality for a nominal 1R entrance exposure. Since risk coefficients for cancer induction by radiation are different for men and women (two studies of radiation-induced carcinogenesis are reviewed including a table of risk coefficients and relative severities for selected organs), the somatic dose indices for radiographic examinations are displayed separately for men and women using different linear scales. Mammographic, thoracic spine (female), and rib (female) examinations have the highest somatic detriment to the individual, under the selected typical conditions. The next level of somatic detriment for both men and women is caused by upper gastrointestinal (GI), barium enema, and lumbosacral spine examinations. When the entire population somatic dose index was calculated, the population somatic detriment associated with mammography is 2 times greater than that for any other examination, followed by male and female upper GI examinations. Two other radiation risks (in utero exposure and genetically significant dose) are briefly reviewed. (18 refs)

79-0342 Chromosome Distribution Study in Peripheral Blood Lymphocytes from X-Ray Exposed Subjects (Meeting Abstract). (Eng) Verschaeve, L. (Laboratorium voor Antropogenetica, Vrije Universiteit Brussels, Brussels, Belgium); Kirsch-Volders, M.; Poma, K.; Hens, L.; Susanne, C. In: *Program and Abstracts of the 12th International Leukocyte Culture Conference held in Beer Sheva, 25-30 June, 1978*. Ben Gurion University of the Negev. (Beer Sheva, Israel): 347 pp.; p. 80; 1978. (no refs)

79-0343 A Second Brain Tumour and Irradiation. (Eng) Robinson, R. G. (Dept. Surgery, Univ. Otago Medical Sch., Dunedin, New Zealand). *J Neurol Neurosurg Psychiatry* 41(11): 1005-1012; 1978.

The cases of three patients who had a primary brain tumor that was managed by radiotherapy and who developed a sec-

and brain tumor of a different type 21 yr or more later are reported. Case 1 was a man born in 1935 who received approx 4,000 rads over 23 days for a mass in the third ventricle in 1945. An 18-g circumscribed pineal teratoma was subsequently removed. In 1971, a right frontal tumor was discovered after complaints of left hemiparesis. Upon necropsy, an extensive astrocytoma Grade 4 (glioblastoma multiforme) was noted. Case 2, a man born in 1915, was treated in 1951 with 2,750 rads over 39 days following removal of a 25-g transitional meningioma from the sphenoidal ridge. After readmission in 1972, a large neoplastic cyst containing 50 ml of xanthochromic fluid was discovered, and it was diagnosed as astrocytoma Grade 3. Case 3, who was born in 1941, received 3,000-3,500 rads to the total nervous system over 3 wk for a cerebellar round-cell tumor in 1953. She was admitted again in 1975 because of visual defects and was diagnosed with a suprasellar meningioma (30-mm in diameter) that had encircled the right optic nerve. Evidence in the literature shows that moderate to high doses of ionizing radiation given in childhood are associated with a late risk of developing a meningioma. There is insufficient evidence to implicate ionizing radiation in the etiology of gliomas. (35 refs)

- 79-0344 Neck Radiation and Hyperparathyroidism (Letter to Editor).** (Eng) Taylor, D. A. (Kaiser Foundation Hosp., Fontana, CA, 92335); Palmer, F. J.; Sawyers, T. M. *Ann Intern Med* 89(6): 1012-1013; 1978.

Of 66 patients with hyperparathyroidism seen over a 4-yr period, 6 (5 women, 1 man) had received previous neck irradiation. Four of these six patients underwent neck exploration: three had solitary parathyroid adenomas and one (the man) had hyperplasia of all four glands. (4 refs)

- 79-0345 Hemangiosarcoma Subsequent to Radiotherapy for a Hemangioma in Infancy.** (Eng) Bennett, R. G. (Emory Univ. Clinic, 1365 Clifton Road, Atlanta, GA, 30322); Keller, J. W.; Ditty, J. F. *J Dermatol Surg Oncol* 4(11): 881-883; 1978.

A 31-yr-old white man developed a hemangiosarcoma at the site of a hemangioma that had been treated 30 yr previously by x-rays. Only two similar cases could be found in the literature. (19 refs)

- 79-0346 A Review of One Hundred and Fifty Thyroidectomies Following Prior Irradiation to the Head, Neck, and Upper Part of the Chest.** (Eng) Wagner, D. H. (Chicago, IL); Recant, W. M.; Evans, R. H. *Surg Gynecol Obstet* 147(6): 903-908; 1978.

The records of 150 patients who had received prior irradiation to the head, neck, and upper part of the chest and who

subsequently underwent thyroid surgery due to identification of nodules upon technetium thyroid scan or palpation were analyzed. Most patients were 20-40 yr old, and approx 66% had been irradiated between the ages of 2 and 6. There were 48 thyroid carcinomas in this series, of which only 17 were recognized preoperatively or at operation. Eighteen other gross lesions were diagnosed on permanent sections, and 13 occult carcinomas diagnosed only after microscopic examination of thyroid tissue. The male:female ratio in both the benign and malignant tumor groups was 1:1, and the latent period from radiation exposure to time of operation for both groups was approx 20-30 yr. Of the 30 carcinoma patients who had a total thyroidectomy, 16 originally underwent a lesser procedure and required reoperation when carcinoma was confirmed on permanent sections. Of these 16 patients, 11 had residual carcinoma: 3 in the same lobe, 6 in the opposite lobe, and 2 in both lobes. This finding confirms the multifocal nature of the disease. The technetium scan was reliable for identifying thyroid nodules; physical examination was less accurate. (11 refs)

- 79-0347 Laryngeal Malignancy Following Iodine-125 Therapy for Thyrotoxicosis.** (Eng) McKillop, J. H. (Univ. Dept. Medicine, Royal Infirmary, Glasgow G4 0SF, Scotland); Doig, J. A.; Kennedy, J. S.; Thomson, J. A.; Greig, W. R. *Lancet* 2(8101): 1177-1179; 1978.

The development of an unusual laryngeal malignancy (spindle cell sarcoma) in a patient who received iodine-125 therapy is reported. A 52-yr-old woman presented with a laryngeal sarcoma 8 yr after receiving two 30-mCi doses of ^{125}I for thyrotoxicosis. The facts that extrathyroidal tissue receives a higher radiation dose of low-energy photon radiation from ^{125}I than from an equivalent microcurie dose of iodine-131 and that the tumor was of a type that rarely arises spontaneously in the larynx suggest a possible link between the development of the tumor and ^{125}I therapy. (16 refs)

- 79-0348 Late Radiation Effects in the Thyroid Gland: A Severe Sequela of Reactor Accidents.** (Swe) Walinder, G. (Natl. Defense Res. Inst., S-172 04 Sundbyberg, Sweden). *Lakartidningen* 75(25): 2479-2480; 1978.

An increased incidence of benign tumors and cancer of the thyroid gland was observed in the population of the Marshall Islands 22 yr after exposure to radioiodine following an atomic bomb test. The calculated thyroid dose was 139-137 rads. (no refs)

- 79-0349 Thyroid Gland Formation from Inocula of Monodispersed Cells: Early Results on Quantitation, Function, Neoplasia and Radiation Effects.** (Eng) Clifton, K. H. (Radiobiology Laboratories, Dept. Human

Oncology, Wisconsin Clinical Cancer Center, Univ. Wisconsin Medical Sch., Madison, WI, 53706); DeMott, R. K.; Mulcahy, R. T.; Gould, M. N. *Int J Radiat Oncol Biol Phys* 4(11/12): 987-990; 1978.

The results of a quantitated injection of monodispersed thyroid cells into the inguinal fat pads and the interscapular white fat pad of histocompatible thyroidectomized Fischer rats were studied. One group of animals was given a low-iodine diet and deionized water after grafting, and some of these animals were also given ^{125}I -iodine ip 6 hr before killing. Radioiodine uptake at the graft site was correlated with the number of cells inoculated and with increase in body wt after grafting. Irradiation of the cell suspension prior to grafting increased the number of cells necessary to achieve a particular degree of radioiodine uptake. Functional thyroid follicles developed at the graft sites, the number being related to the number of thyroid cells injected. These thyroid structures were able to concentrate iodine and support body growth. Two carcinomas and five adenomas developed in seven rats that received irradiated cells and adenomas developed in two rats that received nonirradiated cells. One of the carcinomas was highly undifferentiated and had metastasized to the lungs. (12 refs)

79-0350 Aerodynamic and Dissolution Behavior of Fume Aerosols Produced During the Combustion of Laser-ignited Plutonium Droplets in Air. (Eng) Raabe, O. G. (Dept. Radiological Sciences, Sch. Veterinary Medicine, Univ. California, Davis, CA, 95616); Teague, S. V.; Richardson, N. L.; Nelson, L. S. *Health Phys* 35(5): 663-674; 1978.

The aerodynamic and dissolution properties of fume aerosols produced by high temperature burning in air of single 50-500 μm -diameter droplets of gallium-stabilized, delta-phase plutonium (Pu) metal ignited with a laser were studied. Mass balance and aerosol measurements demonstrated that essentially all the Pu lost from the burning droplet (up to 40%) became aerosolized. Electron microscopy showed that these aerosols consisted primarily of web-like chains of ultrafine crystalline (cubical) particles (4-100 nanometers on side) and a few nearly spherical, discrete particles as large as 0.5 μm . Aerodynamic size distribution determined by using both the cascade impactor and spiral duct centrifuge samplers indicated that these aerosols were in the respirable range with activity median aerodynamic (resistance) diameters of 1-2 μm . In vitro dissolution studies demonstrated higher dissolution rates than normally exhibited by plutonium oxide; the expected dissolution half-time for the fume aerosols was predicted to be 100-700 days depending upon unit particle sizes. These shorter-than-expected half-times suggest that small particulate components become mobilized in the dissolution solvent. Such small particles could pass into the blood capillaries from the lung if inhaled and would be expected to have chemically reactive surfaces, as if chemical dissolution had occurred. (39 refs)

79-0351 Short-Term Metabolism of Inhaled Monodisperse $^{239}\text{PuO}_2$ in the Dog: Effect of Particle Size (Meeting Abstract). (Eng) Guilmette, R. A. (Inhalation Toxicology Res. 79-0353 Plutonium Aerosol Characterization Inside Safety Enclosures at a Demonstration Mixed-Oxide Fuel Fabrication Facility. (Eng) Raabe, O. G. (Radiobiology Lab., Univ. California, Davis, CA); Newton, G. J.; Wilkinson, C. J.; Teague, S. V.; Smith, R. C. *Health Phys* 35(5): 649-661; 1978.

The atmospheres inside glove boxes in which plutonium oxide and uranium oxide were being used to fabricate reactor fuel pellets were sampled. A seven-stage cascade impactor was used to determine the aerodynamic size distribution and concentration, a spiral-duct aerosol centrifuge was used to study the characteristics of the particles with respect to aerodynamic equivalent size, and a point-to-plane electrostatic precipitator was used to take samples for electron microscopy. The median gross alpha activity concentrations in the glove box determined with the impactor samples was 45 nCi/liter. Alpha spectroscopy showed that the alpha activity was uniformly associated with two distinct energy peaks, one representing the ^{239}Pu - ^{240}Pu (5.1 megaelectronvolts (MeV)) and one representing ^{238}Pu and ^{241}Am (5.5 MeV). In the powder-mixing operation, the aerosol size distributions had activity median aerodynamic diameters (AMAD) of 1.9 μm and geometric standard deviations of 1.59. For the centerless grinding operation, the size distribution had an AMAD value of 2.3 μm and geometric standard deviation of 1.6. Some of the aerosols had sufficient electrostatic charge to alter sample collection if a discharger was not used. In vitro measurement of dissolution in a lung simulant predicted a half-time for inhaled material from the blending-mixing operation of 28-200 days and from the centerless grinding operation of 3-6 yr. Thus, both types of particles demonstrated higher solubility than reported for laboratory aerosols of high temperature-treated $^{239}\text{PuO}_2$. (10 refs)

79-0354 Urinary Plutonium Excretion Following Plutonium Exposure (Meeting Abstract). (Eng)

79-0355 Attenuation of 13-20 keV Photons in Tissue Substitutes and Their Validity for Calibration Purposes in the Assessment of Plutonium in Lungs. (Eng) Newton, D. (Environmental and Medical Sciences Div., Atomic Energy Res. Establishment, Harwell, Didcot, Oxon, England); White, D. R. *Health Phys* 35(5): 699-703; 1978.

The attenuation properties of 26 tissue substitutes for 13-20 kiloelectronvolt (keV) x-rays were compared with those of tissues encountered in the human thorax. Partial linear attenuation coefficients μ (for Compton scattering) and μ (for photoelectric interactions) were evaluated at 13.6, 17.2 and 20.2 keV. The selection of tissue substitutes that are valid for 13-20 keV radiation is predominantly a matter of matching photoelectric attenuation coefficients; Compton scattering is a relatively unimportant process of attenuation. Materials were deemed to be valid substitutes for the soft tissues of the chest wall (muscle, adipose tissue, breast, cartilage) if μ was correct to within 3% at 17.2 keV and to within 5% at 13.6 keV and 20.2 keV. The same criterion was adopted for liver and heart, even though it is probably unduly restrictive. On this basis, substitute materials for the various tissues in the human thorax are suggested, eg, Perspex (assumed to be polymethyl methacrylate) for breast tissue, latex (foamed) for liver, and polyurethane plus 4.3% calcium carbonate for heart. None of the materials examined provided a close match for the attenuation data of bone marrow. This comparison also indicated that certain substitutes used in various assessments of plutonium in the lung have been inappropriate and that the use of Alderson lung substitute contributed substantially to errors made in estimating paladium-103 in vivo. 79-0359 Distribution of ^{238}Pu in Tissues of Fish from the Canal in Miamisburg, Ohio. (Eng) Kennedy, C. W. (Ecological Sciences Section, Radiological and Environmental Res. Div., Argonne Natl. Lab., Argonne, IL, 60439); Bartelt, G. E. *Environ Res* 17(2): 228-235; 1978.

^{238}Pu concentrations were determined in the tissues of seven species of freshwater fish taken from the abandoned Miami-Erie canal in Miamisburg, Ohio. The canal contained elevated ^{238}Pu levels as a result of a spill from a Pu fabrication facility in 1969. Gizzard shad, black bullheads, carp, bluegills, black crappies, smallmouth bass, and largemouth bass were collected and various tissues were analyzed. Similar analyses were made of 100 hatchery bluegills artificially introduced into the canal. The mean ^{238}Pu concentration was 0.71 and 5.28 picocuries/liter in filtered canal water and suspended sediments, respectively. The highest ^{238}Pu levels were found in the gastrointestinal (GI) tracts and gills, the lowest levels in muscle. A rapid uptake of ^{238}Pu was observed for the hatchery bluegills. The high Pu concentrations in the GI tracts and gills suggest that these organs are potential uptake sites. The presence of ^{238}Pu in liver, gonads, bone, and muscle indicates that ^{238}Pu is translocated from the uptake sites. The high Pu concentrations in liver and increased concentrations in the bodies and GI tracts of the hatchery bluegills (which apparently were not feeding) suggest the existence of an uptake pathway other than ingestion of food and support the translocation concept. - 79-0363 Inhalation Carcinogenesis of High-Fired $^{244}\text{CmO}_2$ in Rats.** (Eng) Sanders, C. L. (Biology Dept., Pacific Northwest Lab., Richland, WA, 99352); Mahaffey, J. A. *Radiat Res* 76(2): 384-401; 1978.

The carcinogenicity of inhaled $^{244}\text{CmO}_2$ in the lung and bone of 277 female Wistar rats was determined. The rats were divided into five groups and exposed for 30 min to alveolar deposition levels of 0.54, 4.4, 48, 450, and 1,800 nanocuries (mCi) of ^{244}Cm . An additional 118 rats served as unexposed controls. The activity median aerodynamic diameter of the aerosol was $0.8\ \mu\text{m}$. The distribution of ^{244}Cm on autoradiograms of lung taken immediately and up to 2 yr after inhalation exposure was similar, with mostly single α tracks and only occasional α stars. Approx three-fourths of the alveolarly deposited ^{244}Cm was cleared from the lung with a half-life of 0.5 day, one-fourth with a half-life of 12 days; approx 2% was retained with a half-life of about 1 yr. ^{244}Cm uptake by bone reached a max by 50 days and who showed no change thereafter. The retention half-life of ^{244}Cm in liver and thoracic lymph nodes was < 2 wk. Rats exposed to 450 and 1,800 nCi experienced significantly increased early mortality due to radiation pneumonitis. A significant incidence of adenomatous metaplasia occurred in the 450-nCi group only; no cases of metaplasia were observed in the 1,800-nCi group. All but one of the induced lung tumors were adenocarcinomas, the exception being a squamous cell carcinoma in the 450-nCi group. Lung tumor incidence in the five respective dose groups was 1.8%, 1.7%, 13%, 32%, and 0%; no tumors occurred in controls. A significantly increased number of bone and lung tumors were found with the 48- and 450-nCi doses. On an av lung dose basis, the dose-response pattern for the induction of pulmonary adenocarcinoma from inhaled $^{244}\text{CmO}_2$ was similar to that observed for inhaled $^{239}\text{PuO}_2$, despite large differences in particle size, solubility, and alveolar clearance. (43 refs)

- 79-0364 The Retention and Distribution of ^{243}Cm and ^{244}Cm in C57BL/Do Mice.** (Eng) Smith, J. M. (Radiobiology Lab., Univ. Utah Coll. Medicine, Salt Lake City, UT, 84112); McFarland, S. S.; Calder, S. E.; Mays, C. W. *Radiat Res* 76(2): 436-440; 1978.

The whole-body retention (WBR) and tissue distribution of ^{243}Cm and ^{244}Cm were determined in 48 10-mo-old C57BL/Do mice for up to 297 days after they were inoculated with $3.5\ \mu\text{Ci/kg}$ ^{243}Cm and ^{244}Cm in 0.8 M citrate soln. The activity distribution at the time of injection was 57.6% ^{244}Cm and 42.3% ^{243}Cm . WBR was determined periodically by photon counting of the ^{243}Cm γ emission using dual 20 x 10-cm NaI(Tl) detectors. Mice were sacrificed on days 3, 14, 56, 91, and 182 postinjection, and tissue distribution of Cm in the liver, femurs, kidneys, spleen, and skeleton was determined. The WBR of ^{243}Cm and ^{244}Cm was significantly higher in males than in females, in agreement with previous studies using ^{239}Pu . Most ($> 76\%$) of the body burden of Cm was found in the liver and skeleton. From 3 to 182 days postinjec-

tion, the skeletal burden was nearly constant, averaging 25% of the injected Cm for males and 21% for females. On day 3 postinjection, the kidneys of both sexes contained 0.52% of the injected Cm, the spleen 0.02%. Further comparison of the Cm and Pu studies showed that the WBR and skeletal retention of Cm in mice of the same sex was lower than that of Pu. Hepatic retention of Cm was similar, with retained activity being higher in males. (8 refs)

- 79-0365 Dose-Response Relationships for Female Radium Dial Workers.** (Eng) Rowland, R. E. (Center Human Radiobiology, Argonne Natl. Lab., Argonne, IL, 60439); Stehney, A. F.; Lucas, H. F. *Radiat Res* 76(2): 368-383; 1978.

The probability of the separate induction of bone sarcomas and carcinomas originating in the mastoid air cells or paranasal sinuses (head carcinomas) as a function of radium dose was determined using data on 759 female radium-dial workers employed before 1930. The relative effectiveness of ^{226}Ra and ^{228}Ra and dose-incidence relationships were examined for these women, whose Ra body burden had been determined. There were 38 bone sarcomas and 17 head carcinomas in this group. Incidence was expressed as tumor cases per person-year, and the dose parameter was the quantity of Ra that entered the blood during the exposure period. Equations were fitted to the observed data for each tumor type; for each equation, the best dose-coefficient values were found by a least-squares fitting procedure. The bone sarcoma data were best described by a dose-squared exponential function, which predicts 0.24 bone sarcoma/yr among the 32 high-intake ($> 100\ \mu\text{Ci}$) surviving women and 0.006 bone sarcoma/yr among the 331 low-intake ($0.5\text{-}99\ \mu\text{Ci}$) survivors. Head carcinoma data were best described by a linear equation that predicts 0.1 case/yr for 50 surviving women exposed to $\geq 25\ \mu\text{Ci}$ and 0.02 case/yr for 294 women exposed to $0.5\text{-}24.9\ \mu\text{Ci}$. Dose-incidence equations obtained when dose was expressed as av skeletal dose in rads are also given. (28 refs)

- 79-0366 ^{222}Rn Daughter Dosimetry in the Syrian Golden Hamster Lung.** (Eng) Desrosiers, A. (Yankee Atomic Electric Co., 20 Turnpike Rd., Westboro, MA, 01581); Kennedy, A.; Little, J. B. *Health Phys* 35(5): 607-623; 1978.

Data obtained from a detailed morphometric description of the dimensions of airways, the branching patterns, and the epithelial cell frequencies in the respiratory tract of the Syrian golden hamster were used to construct a mathematical model of the deposition of inhaled particles and their subsequent regional translocation during extracellular lung clearance. Mucus velocity and particulate deposition were calculated for the trachea, for eight groups of conductive airways, and for the alveolated portion of the lung. The number of polonium (Po)-218 and ^{214}Po disintegrations per year was calculated for

each airway group using reference radon-222 (Rn)-laden atmospheres. The depth-dose distribution in the epithelial tissues of the airways was derived for each alpha particle energy. The dose to basal cells in the subsegmental bronchi is 0.4-1.6 rad per working level year (WLY). The mean dose to basal cells and Clara cells is 2.3 rad/WLY. Since Clara cells have been implicated in hamster lung carcinogenesis, the dose to these differentiated cells may be relevant to tumor induction. In contrast, models of the human lung suggest that the highest dose to all types of cells is in the higher airways (subsegmental bronchi) and that the cancer-related dose is 3-20 rad/WLY for identical ^{222}Rn -laden atmospheres. 79-0369 Effect of Dose Distribution on the Induction of Experimental Lung Cancer by Alpha Radiation. (Eng) Little, J. B. (Dept. Physiology, Harvard Univ., Sch. Public Health, Boston, MA, 02115); Kennedy, A. R.; McGandy, R. B. *Health Phys* 35(5): 595-606; 1978.

The relative carcinogenicity of polonium-210 (^{210}Po) administered intratracheally by two different methods was studied in female Syrian golden hamsters. In one method, ^{210}Po was instilled in soluble form in a saline solution giving a uniform distribution of radioactivity throughout the lung parenchyma. In the other, Po was administered adsorbed onto ferric oxide (Fe_2O_3)-carrier particles yielding a non-uniform distribution; most of the ^{210}Po - Fe_2O_3 particles were retained in the peripheral lung, surrounding terminal and respiratory bronchioles. With lifetime doses averaged over the whole lungs of 55-2700 rad, the tumor yields for the non-uniform irradiation were less than or equal to those for uniform exposure. At low radiation doses, 9/99 animals that had received ^{210}Po alone in saline (55 rad dose) developed lung tumors while 10/75 that had received ^{210}Po - Fe_2O_3 (75 rad) developed tumors. At high radiation doses (1,500-2,700 rad), 22/38 animals that received ^{210}Po alone developed lung tumors while 39/71 that received ^{210}Po - Fe_2O_3 developed lung tumors. In the high-dose group, the life span of tumor-bearing animals was markedly reduced while there was no significant difference from controls in the low-dose groups. There was no significant differences in the histopathologic characteristics

of the tumors induced by either Po treatment. These findings indicate that the assessment of the hazards of inhaled alpha emitters using a model based on uniform distribution is a reasonable approach for radiation protection purposes. (22 refs)

79-0373 Absence of Interaction Between X-Rays and UV Light in Inducing Ouabain- and Thioguanine-Resistant Mutants in Chinese Hamster Cells. (Eng) Cleaver, J. E. (Lab. Radiobiology, Univ. California, San Francisco, CA). *Mutat Res* 52(2): 247-253; 1978.

In an effort to detect an inducible error-prone repair system in eukaryotic cells, Chinese hamster ovary cells were sequentially irradiated with x-rays and UV light. The rationale of the protocol was that the x-rays would induce the error-prone system, and UV light would then produce more mutations than if used alone. However, no synergism was noted in the ability of the two treatments to produce ouabain or 6-thioguanine resistance in these cells, suggesting that no error-prone repair system exists. Monolayers of approx 10^6 cells were irradiated with 300 rad of x-ray, allowed to grow for up to 17 hr, and then irradiated with 13 Joule (J)/meter² (m²) of 254 nanometer UV light. Cells were kept in exponential growth for 6 days, and then incubated (5×10^5 cell/ml) with 3 mM ouabain or 0.06 mM 6-thioguanine for 7-8 days, at which time the av mutation frequencies were determined. Linear dose-response relationships were noted for both drug resistance markers independently (yields of 1.3×10^{-7} /rad and 3.6×10^{-5} /J/m² for 6-thioguanine and 1.0×10^{-6} /J/m² for ouabain); when both radiation types were applied, no synergism was noted for any time interval between irradiation treat-

ments up to 17 hr. The failure to detect a synergism of action in these treatments may indicate that the mechanisms by which mutations are produced by errors in replication and repair may be constitutive in eukaryotic cells in contrast to the inducible systems in prokaryotes. (25 refs)

- 79-0374 Induction of 6-Thioguanine- and Ouabain-resistant Mutations in Synchronized Syrian Hamster Cell Cultures During Different Periods of the S Phase.** (Eng) Tsutsui, T. (Div. Biophysics, Sch. Hygiene and Public Health, Johns Hopkins Univ., Baltimore, MD, 21205); Barrett, J. C.; Ts'o, P. O. *Mutat Res* 52(2): 255-264; 1978.

The temporal replication of genes responsible for 6-thioguanine (6TG) and ouabain (OB) resistance was examined in cells of a transformed Syrian hamster line, BP6T, following synchronization, selective incorporation of 5-bromodeoxyuridine (BUdR) during specific portions of the S phase, and mutagenesis by light. The cells were synchronized by a period of growth in low serum, with subsequent blockage of the cells at the G₁/S boundary by hydroxyurea. This method provided cells with nearly 100% synchrony, although approx 20% of the cells were noncycling. The cells were then treated with 10⁻⁵ M BUdR for one of five 1-hr periods of the S phase and then irradiated with near-UV light for 5 min. BUdR + UV light induced 6TG and OB-resistant mutants, but BUdR or irradiation alone was not mutagenic. 6TG-resistant mutants were induced only during the early S phase by BUdR + UV light, but OB-resistant mutants were induced in a biphasic pattern, during early S and late S. The latter finding may indicate the presence of two genes specifying Na⁺/K⁺ ATPase that were replicated at distinct periods during S. (30 refs)

- 79-0375 Perturbations in Simian Virus 40 DNA Synthesis by Ultraviolet Light.** (Eng) Williams, J. I. (Lab. Radiobiology, Univ. California, San Francisco, CA); Cleaver, J. E. *Mutat Res* 52(3): 301-311; 1978.

The effects of UV irradiation (254 nanometers) on simian virus 40 (SV40) DNA synthesis in African green monkey kidney cells were studied during the period of max viral DNA synthesis. DNA synthesis was suppressed to 61% of control values at 20 joules (J)/m² and to 49% of control values at 40 J/m². The amount of ³H-thymidine label in Form I DNA molecules was very sensitive to UV light, whereas incorporation into replicative intermediate and Form II molecules was less sensitive, a finding consistent with inhibition of DNA chain elongation. The observed amounts of label incorporated into irradiated molecules could be predicted based on the assumption that pyrimidine dimers are responsible for blocking nascent DNA strand growth. The relative proportion of labeled Form I molecules in irradiated cultures rapidly increased to near control values with incubation after exposure to 20 or 40 J/m² of UV light (0.9-1.0 or 1.8-2.0 dimers/SV40

genome, respectively). This rapid increase and the failure of Form II molecules to accumulate suggest that SV40 growing forks can rapidly bypass many dimers. Form II molecules formed after irradiation were not converted to linear (Form III) molecules by the dimer-specific T4 endonuclease V, suggesting that there are no gaps opposite dimers in these molecules or that T4 endonuclease V cannot use Form II molecules as substrates. (41 refs)

- 79-0377 Contribution of a Caffeine-Sensitive Recombinational Repair Pathway to Survival and Mutagenesis in UV-irradiated *Schizosaccharomyces pombe*.** (Eng) Genter, N. E. (Biology and Health Physics Div., Atomic Energy Canada Ltd., Chalk River Nuclear Lab., Chalk River, Ontario, Canada); Werner, M. M.; Hannan, M. A.; Nasim, A. *Mol Gen Genet* 167(1): 43-49; 1978.

The role of a caffeine-sensitive recombinational process in repair of UV-induced damage in *Schizosaccharomyces pombe* was studied. G1 and G2 phase cells of wild-type *S. pombe* showed caffeine-induced lethal enhancement after UV irradiation. G1 cells were considerably more UV-sensitive than G2 cells, the resistance of the latter apparently being primarily related to the possession of a duplicated genome at the time of irradiation. The UV-sensitization by caffeine was abolished in G1 and G2 cells by the *rad1* mutation, which substantially reduces recombination following UV treatment. UV-irradiated wild-type G1 cells displayed a lag time of approx 8 hr before caffeine-sensitive repair began, and recovery was seen only after DNA synthesis had commenced. The caffeine-sensitive repair process began immediately in UV-irradiated G2 cells, however. *Rad* mutants, which show a higher UV-induced mutation rate than do wild-type cells, retained the caffeine-sensitive UV-repair process, whereas *rad* strains were relatively UV-immutable compared with the wild-type strain, which did not. The recombinational process may therefore be the major pathway responsible for UV-induced mutation in *S. pombe*. (25 refs)

79-0381 Modification of UV-induced Mutation Frequencies in Chinese Hamster Cells by Dose Fractionation, Cycloheximide and Caffeine Treatments. (Eng) Chang, C. C. (Dept. Human Development, Coll. Human Medicine, Michigan State Univ., E. Lansing, MI, 48824); D'Ambrosio, S. M.; Schultz, R.; Trosko, J. E.; Setlow, R. B. *Mutat Res* 52(2): 231-245; 1978.

Experiments were designed to determine if an inhibition of enhanced postreplication repair led to modifications in the production of UV-induced ouabain-resistant mutations in Chinese hamster V79 cells. The cells were irradiated with a fractionated dose of UV light (first dose, UV₁, 3 joules/m², followed 4-6 hr later by UV₂, 17 joules/m²). Fractionation of the UV dose always increased the colony-forming ability of these cells, but mutation frequency was either reduced or not changed. Cyclohexamide (CH) treatment (5 µg/ml) for 12 hr between irradiations reduced colony-forming ability and increased mutation frequency, whereas a 4-hr treatment between irradiations had the opposite effect. When the cells were treated with CH for 3 hr immediately after UV₁ (followed by no treatment for 3 additional hours before UV₂) reduced colony-forming ability and increased mutation frequency resulted, but when CH treatment was shifted closer in time to UV₂, this effect was diminished or even reversed. Like CH, caffeine treatment (1 mM) for 6 or 12 hr between UV treatments reduced colony-forming ability and increased mutation frequency. When added immediately after UV₁, caffeine treatment for 2, 4, and 6 hr progressively inhibited postreplication repair by UV fractionation 48%, 62%, and 100%, respectively. The results suggest that an error-free postreplication repair system exists in Chinese hamster cells that can be inhibited by particular CH or caffeine treatments. (41 refs)

79-0382 Effect of Caffeine on Ultraviolet Mutagenesis in V79 Chinese Hamster Cells. (Eng) Tatsumi,

M. (Dept. Radiation Biophysics, Kobe Univ. Sch. Medicine, Kusunoki-cho 7-12, Ikuta-ku, Kobe 650, Japan); Fujiwara, Y. *Gann* 69(5): 727-730; 1978.

The effect of caffeine on induction of 6-thioguanine-resistant (6TGr) colonies in V79 Chinese hamster cells by UV irradiation (254 nanometers) was examined by the replating method. Post-UV treatment with 1 mM caffeine had neither a synergistic nor suppressive effect on the induced 6TGr frequency, in contrast to a marked killing potentiation as a result of inhibition of replicative repair. This suggests a possible involvement of repair mechanism(s) other than replicative repair in UV mutagenesis. (25 refs)

79-0383 Ultraviolet Light Induction of Skin Carcinoma in the Mouse; Influence of cAMP Modifying Agents. (Eng) Zajdela, F. (Unité No. 22 de l'INSERM, Physiologie Cellulaire, Institut du Radium, Batiment 110, Faculté des Sciences, F 91405 Orsay, France); Latarjet, R. *Bull Cancer (Paris)* 65(3): 305-313; 1978.

A review is presented concerning the carcinogenic effect of UV irradiation on mice to introduce current experiments in which cyclic AMP (cAMP)-modifying agents were examined for their effects on UV-induced skin carcinogenesis that might result from their inhibition of DNA repair synthesis. Swiss (Carshalton) specific pathogen-free female mice were used in this study, which employed the same conditions used in previously reported studies on DNA repair inhibitors. Caffeine, theophylline, reductone (tartronic aldehyde), chloroquinone, papaverine, 3-isobutyl-1-methylxanthine (IBMX), uridine, or N-2'-O-dibutyryladenine-3'-5' cyclic monophosphoric acid (db-cAMP) were applied (40 µl of 1% or 2% soln) to one ear of a mouse before each of 133 treatments of 7.3 x 10³ Joules (J)/meter² (m²) UV irradiation (a total irradiation of 1 x 10⁶ J/m²). Whereas caffeine and theophylline reduced tumor incidence in the skin of the ear by approx 50%, reductone and chloroquinone had no effect. Likewise, uridine, a UV-absorbing compound, was also ineffective in reducing tumor number. The phosphodiesterase inhibitors IBMX and db-cAMP were not able to alter tumor yields, and papaverine, inhibited tumor yield only slightly and insignificantly (89%-73%). These results offer no support to the hypothesis that the abilities of caffeine and theophylline to inhibit tumor growth are related to their known abilities to inhibit phosphodiesterase and therefore to increase total cellular cAMP levels. The experiments do suggest that UV carcinogenesis is related to postreplication DNA repair, which favors the occurrence of errors in cellular DNA sequences. (59 refs)

79-0384 Cell Transformation by Non-Coherent Ultraviolet-Visible Light Radiation (Meeting Abstract). (Eng) Withrow, T. J. (Bureau Radiological Health, Food and Drug Admin., Dept. Health, Education and Welfare, Rockville, MD, 20857). *Health Phys* 35(6): 891; 1978. (no refs)

79-0386 Photodynamic Effect of Proflavine on ϕ X174 Bacteriophage, Its DNA Replicative Form and Its Isolated Single-stranded DNA: Inactivation, Mutagenesis and Repair. (Eng) Piette, J. (Lab. General and Medical Microbiology, Univ. Liege, Sart Tilman, B-4000 Liege, Belgium); Calberg-Bacq, C. M.; Van de Vorst, A. *Mol Gen Genet* 167(1): 95-103; 1978.

Repair of lesions induced by treatment with UV light plus proflavine was studied using single- and double-stranded bacteriophage ϕ X174 DNA. The infectivity of the double-stranded ϕ X replicative form (RF)I DNA was about 10-fold more sensitive to treatment with proflavine and light than was isolated ϕ X single-stranded (ss) DNA. The photodynamic inactivation of ϕ XRFI DNA appeared to be caused by intercalated dye molecules. With ϕ XRFI DNA, ϕ X ss DNA, and intact ϕ X174 phages, reactivation occurred through high multiplicities of infection and depended on the cellular rec A gene product. The pol A, uvr A, and lex A gene mutations had no effect on phage or DNA inactivation rates. The photodynamically induced lesions could be at least partially repaired by the SOS repair system induced in *Escherichia coli* host cells by irradiation with 100 Joules/meter². SOS repair did not occur in bacteria or spheroplasts irradiated in the presence of chloramphenicol. Reversion frequency of ϕ X174 amber mutations indicated that: (1) photodynamically induced lesions were mutagenic whether or not the rec A gene product was present in the indicator bacteria, (2) induction of the SOS repair system was accompanied by a mutagenic process resulting in a nearly two-fold increase in reversion frequency, and (3) multiplicity reactivation occurred through a recombinational process and was not mutagenic per se. (41 refs)

79-0387 Identification and Cytotoxic Reactivity of Inflammatory Cells Recovered from Progressing or Regressing Syngeneic UV-induced Murine Tumors. (Eng) Lill, P. H. (Dept. Pathology, Sch. Medicine, Univ. South Carolina, Columbia, SC, 29208); Fortner, G. W. *J Immunol* 121(5): 1854-1860; 1978.

The histologic appearance of tumors during progressive growth in UV-irradiated mice and during regression in normal mice was examined, and the composition and in vitro reactivity of the inflammatory cell infiltrates that could be recovered from the tumors after transplantation into these two types of recipients were compared. Syngeneic UV-induced fibrosarcomas were implanted sc bilaterally in normal

C3H/HcN(MTV-) mice (regressor animals) and in mice irradiated with 2.8 joules/m²/sec of UV light (280-340 nm) for 1 hr 3x/wk for 3-4 mo (progressor animals). At 2, 4, 6, 8, and 10 days postimplantation, tumor fragments were recovered for immunofluorescence, morphologic, and/or in vitro cytotoxicity tests. In both groups, an inflammatory filtrate of mononuclear cells and granulocytes was evident on days 2-6; by days 8-10 however, tumor cell death was evident in regressor animals, but not in UV-treated animals, whose tumors grew in size. At day 6, regressor tumors had a significantly increased lymphocyte/macrophage ratio, and immunofluorescence detected a threefold increase of T cells in regressor vs progressor tumors. Tumor lymphocytes isolated from regressor tumors at this time demonstrated significant cytotoxicity at a 1:1 effector cells:target cell ratio, but progressor lymphocytes were not cytotoxic at this ratio. Treatment of tumor cells from normal mice with anti- μ serum and complement reduced the number of T cells by 65% and cytotoxicity by 72%. Although tumor fragments were not cytotoxic before implantation, by day 4, the T-cell number in regressor tumors had increased 20 times, indicating that almost all B and T cells recovered from implanted fragments were of host origin. The inability of UV-treated mice to destroy syngeneic UV-induced tumors in vivo is apparently related to a decreased ability to mobilize T cells into the tumor and to generate cytotoxic reactivity against the tumor. 79-0388 An Effect of Cell-Cycle Position on Ultraviolet-Light-induced Mutagenesis in Chinese Hamster Ovary Cells. (Eng) Riddle, J. C. (Oak Ridge Graduate Sch. Biomedical Sciences, and Biology Div., Univ. Tennessee, Oak Ridge, TN, 37830); Hsie, A. W. *Mutat Res* 52(3): 409-420; 1978.

The importance of cell-cycle position in UV light-induced mutagenesis was studied using Chinese hamster ovary (CHO) cells. Populations in different stages of the cell cycle were exposed to 10 joules (J)/m². Survival decreased as the cells moved from the G₁ to the S phase, reaching a minimum 30% to 50% through the DNA synthetic period, and then rose threefold to approx 60% during the latter part of S into G₂ and mitosis. Mutation induction was generally lowest as the cells initiated DNA synthesis, rising to a max 1-2 hr into S; mitotic and very early G₁ cells appeared to be somewhat less sensitive to the mutagenic effects of UV. Fluence-response curves obtained at several times during the cell cycle yielded D_q (fluence at which the back extrapolate of the exponential portion of the curve intersects the 100% survival abscissa) values of approx 6 J/m². The primary survival characteristic that varied with cell-cycle position was D₀ (fluence required to reduce survival by a factor e⁻¹ along the exponential portion of a survival curve), which ranged from 2.5 J/m² at 6 hr after mitotic selection to 5.5 J/m² 11 hr afterward. The optimum phenotypic expression time for induced 6-thioguanine resistance was 7-9 days and was essentially independent of both UV fluence and position in the cell cycle. Hypoxan-

thine-guanine phosphoribosyltransferase activity was reduced in all mutants, but it did not differ among mutant clones that had been induced during different cell-cycle phases. Changes in cellular morphology during cell-cycle traverse did not contribute to the differential susceptibility to UV-induced mutagenesis. (40 refs)

- 79-0389 Preleukemia (Haemopoietic Dysplasia) Developing in a Patient with Psoriasis Treated with 8-Methoxypsoralen and Ultraviolet Light (PUVA Treatment).** (Eng) Wagner, J. (Medical Dept. C., Univ. Hosp., Gentofte, DK-2900 Hellerup, Denmark); Manthorpe, R.; Philip, P.; Frost, F. *Scand J Haematol* 21(4): 299-304; 1978.

The development of a preleukemic condition following treatment of psoriasis with psoralen and UV (PUVA treatment) is reported. The patient, a 73-yr-old man with psoriasis of long standing, received 8-methoxypsoralen (30 mg po) and 2 hr later skin irradiation with UV for 10-30 min (2-6 Joule/cm). The treatment was given 4 x/wk for a total of 30 wk (not consecutive). After 1 yr, he developed a preleukemic condition characterized by a refractory anemia, a slight thrombocytopenia and a normo- to hypercellular bone marrow with an excess of myeloblasts (9%-10%). Karyotyping revealed an abnormal chromosome (12P-) and agar cultures of bone marrow showed moderate growth with a high cluster/colony ratio. The patient died 1 yr later of renal failure precipitated by an acute pancreatitis. Although it is impossible to determine whether the development of preleukemia at the time of the psoralen therapy was coincidental or not, the mode of action of PUVA treatment makes it probable that the preleukemia was caused by the PUVA therapy. It is recommended that increased attention be given to the hematopoietic system of patients treated with psoralen. (19 refs)

- 79-0390 Acute Effect of 8-Methoxypsoralen and Ultraviolet Light on Sister Chromatid Exchange.** (Eng) Wulf, H. C. (Dept. Dermatology, Finsen Inst., 49 Strandboulevarden, DK-2100 Copenhagen 0, Denmark). *Arch Dermatol Res* 263(1): 37-46; 1978.

The effects of 8-methoxypsoralen (8-MOP, 10^{-6} mol/liter) and/or longwave UV light (5 or 10 joules/cm²) on the number of sister chromatid exchanges (SCE's) of normal human blood lymphocytes were studied in vitro. The number of SCE's was significantly increased in the presence of 8-MOP + ethanol (in which the 8-MOP was dissolved) without UV irradiation. Ethanol alone also caused a significant increase in SCE's. Irradiation with UV light did not increase the SCE count in the absence of 8-MOP, but irradiation + 8-MOP increased the SCE count by 50% over that seen with 8-MOP alone. UV light + 8-MOP also increased the number of banded stained chromosomes significantly. These changes were dose-dependent, and they might be responsible for the re-

duced cell turnover in psoriasis plaques seen after treatment with both agents. (33 refs)

- 79-0391 The Influence of Inhibitors on Dimer Removal and Repair of Single-Strand Breaks in Normal and Bromodeoxyuridine Substituted DNA of HeLa Cells.** (Eng) Cornelis, J. J. (Laboratoire de Biophysique et Radiobiologie, Universite Libre de Bruxelles, 67 Rue des Chevaux, 1640 Rhode St. Genese, Belgium). *Biochim Biophys Acta* 521(1): 134-143; 1978.

Paper chromatography and immunoautoradiography were utilized to monitor the time course of disappearance of pyrimidine dimers from ³H-thymidine-labeled DNA in HeLa cells irradiated with 254-nanometer UV light. Both techniques gave similar values of the extent and duration of dimer removal. Approx 100% of the removable dimers (approx 50% of all dimers) were released from the cell nuclei within 6 hr when the cells were irradiated at fluences that did not saturate the repair system. The rate of excision was constant throughout most of the cell cycle and was only arrested during mitosis. When 5-fluorodeoxyuridine (FUdR: 10^{-5} M) or 1- β -D-arabinofuranosyl cytosine (10^{-5} M) was added to the postirradiation media, excision was slowed, indicating impairment of the repair function by affecting the available deoxynucleotide pool or by inhibiting DNA polymerases, respectively. When 10% of the thymine in the DNA was replaced by bromodeoxyuridine and the cells were irradiated, the rates of dimer release and repair of single-strand breaks remained the same but occurred to a different extent. On the other hand, FUdR (10^{-5} M) and hydroxyurea (10^{-3} M) inhibited these two processes to the same degree, suggesting that some coordinated repair (perhaps common enzymes) must occur for these two lesions. (40 refs)

- 79-0392 Use of the 5-Bromodeoxyuridine-labelling Technique for Exploring Mechanisms Involved in the Formation of Chromosomal Aberrations. I. G₂ Experiments with Root-Tips of *Vicia faba*.** (Eng) Kihlman, B. A. (Dept. General Genetics, Univ. Uppsala, P.O. Box 7003, S-750 07 Uppsala 7, Sweden); Natarajan, A. T.; Andersson, H. C. *Mutat Res* 52(2): 181-198; 1978.

The ability of long-wave UV light (320-380 nanometers) and x-rays to produce aberrations in chromosomes with 5-bromouracil-substituted DNA was investigated. Chromosomes in the root-tip cells of the field bean (*Vicia faba*) were incubated with 5-bromodeoxyuridine in several schemes to produce chromosomes of the following compositions: TT-TT (both chromatids containing unsubstituted DNA), TT-TB (1 chromatid with unsubstituted DNA, 1 with unifilarly substituted DNA), TB-TB (both chromatids with unifilarly substituted DNA), and TB-BB (1 chromatid with unifilarly substituted DNA, 1 with bifilarly substituted DNA). Sister chromatids of the TT-TB and TB-TB types could be distin-

guished by differential staining. Long-wave UV light induced no aberrations in TT-TT chromosomes. In chromosomes with substituted DNA, the UV light and x-rays induced subchromatid and chromatid aberrations. Exposure of cells to UV light during G₂ produced no increase in sister chromatid exchanges (SCE), but when cells were exposed before or during S, there was a threefold increase of SCE's. Thus, SCE's are formed in connection with DNA and chromosome replication. Sensitivity to aberration production by x-rays increased with increasing number of substituted DNA strands. The increased sensitivity of TB-TB over TT-TB chromosomes was particularly striking. The question of whether a damaged chromatid may interact with an undamaged one to form an exchange was studied based on the finding that in TT-TB chromosomes, long-wave UV light produced no breaks in TT chromatids and x-rays produced about three times as many breaks in TB as in TT chromatids. The results clearly indicate that two lesions are required to produce one exchange. (27 refs)

79-0393 The Chick Embryo Chorioallantoic Membrane as a Bioassay for Angiogenesis Factors: Reactions Induced by Carrier Materials. (Eng) Jakob, W. (AdW der DDR, Institut für Wirkstofforschung, Alfred-Kowalke-Strasse 4, DDR-1136 Berlin, E. Germany); Jentzsch, K. D.; Mauersberger, B.; Heder, G. *Exp Pathol (Jena)* 15(5): 241-249; 1978.

Implantation of a variety of filter materials, sponges, and gels onto chick chorioallantoic membranes produced a local inflammatory reaction with concomitant proliferation of fibroblasts and capillaries. The initiation of the reaction was independent of the type and nature of the material and was even evoked by white eggshell membrane, coagulated albumin, and yolk. This type of vascular reaction cannot be considered characteristic of the action of a particular tumor angiogenesis factor. (17 refs)

79-0394 Cyclic Nucleotide Concentration in Colon Tissue from Wood Fiber and Asbestos Fed Rats (Meeting Abstract). (Eng) Will, L. A. (Dept. Preventive Medicine and Environmental Health, Inst. Agricultural Medicine, Univ. Iowa, Iowa City, IA, 52242); Donham, K. J.; Cole, D. A.; Stevens, R. H. *Cell Tissue Kinet* 11(6): 691; 1978. (no refs)

79-0395 The Effect of Fibre Size on the In Vitro Biological Activity of Three Types of Amphibole Asbestos. (Eng) Brown, R. C. (Medical Res. Council Pneumoconiosis Unit, Llandough Hosp., Penarth, South Glamorgan, CF6 1XW, Wales); Chamberlain, M.; Griffiths, D. M.; Timbrell, V. *Int J Cancer* 22(6): 721-727; 1978.

The effect of fiber size on the in vitro cytotoxicity of crocidolite, amosite, and anthophyllite was assessed. The three samples of amphibole asbestos were subjected to ball-milling, which reduced the length of the fibers present in each sample. The numbers of fibers in unit masses, and the distribution of fiber sizes in all the samples, both parent and milled, were estimated from electron micrographs. The ability of all samples to reduce the plating efficiency of V79-4 cells was compared, on the basis of mass, fiber number, and fiber number above various length thresholds. The biological activity of all samples correlated best with the number of fibers above a threshold length of 6.5 μ m. The toxicity of mineral fibers to V79-4 cells may prove to be a useful model in investigating the nature of the fiber/cell interactions occurring in the induction of tumors by these fibers. If the threshold length of 6.5 μ m is valid, then only about 5% of the fibers in standard (UICC) crocidolite, and 30% in amosite and anthophyllite, are active in this system. (16 refs)

79-0396 Effects of Asbestos on Epithelioid Cell Lines. (Eng) Neugut, A. I. (Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, 701 W. 168 St., New York, NY, 10032); Eisenberg, D.; Silverstein, M.; Pulk-rabek, P.; Weinstein, I. B. *Environ Res* 17(2): 256-265; 1978.

Investigation was made of the effects of asbestos on the growth and viability of two epithelioid cell lines, CHO (a malignant line derived from Chinese hamster ovary) and K-22 (a normal line derived from rat liver), and on the synthesis of plasminogen activator (PA) by these and other cell lines. Relatively low concentrations of asbestos (10 μ g/ml) were quite cytotoxic to both cell lines, with chrysotile (CT) asbestos being more toxic than crocidolite or amosite. Toxicity increased with increasing doses of chrysotile (1-10 μ g/ml). The escape, after several days, of CHO cells from CT toxicity was a consistent finding. The major and irreversible CT cytotoxicity was manifest during the first 24-48 hr of exposure. The escape may have been due to coating of the asbestos fibers by serum proteins or cellular material, or the cells may have adapted to the fibers by phenotypic cell-surface changes. The toxic factor could not be extracted from the asbestos, and toxicity occurred only if there was physical contact between fibers and K-22 and CHO cells. Although the phorbol ester tumor promoters (ie, phorbol-12-myristate acetate) induce PA synthesis in various cell cultures, asbestos did not induce this protease in epithelioid (K-22, CHO, HeLa) or chick embryo fibroblast cell cultures. Thus, PA production may not be related to the cytotoxic effects of asbestos on these cells. The cytotoxic effects of asbestos on K-22 and CHO cells were similar to those observed with macrophages and fibroblasts. It is suggested that toxicity is due to phenomena more complex than simple physical injury to the cell surface and that it may require phagocytosis. (29 refs)

79-0397 Comparison of the Lethal and Mutagenic Effects of Gold and White Fluorescent Lights on

Cultured Mammalian Cells. (Eng) Burki, H. J. (Lawrence Berkeley Lab., Univ. California, Berkeley, CA, 94720); Lam, C. K. *Mutat Res* 54(3): 373-377; 1978.

The lethal and mutagenic effects of gold and white fluorescent lights on cultured mammalian cells were compared. More than 90% of cells exposed to 6×10^4 Joules (J)/meter² (m²) white light underwent reproductive death, whereas even higher doses of gold fluorescent light (GE F30 T8 G0) were without effect. Chronic exposure of CHO cells to white fluorescent light under optimal growth conditions raised the mutation frequency by 5- to 10-fold. The effects of the white fluorescent lights were dramatically enhanced if the tops of the dishes were removed. However, exposure of cells in open dishes to gold fluorescent light caused no additional genetic effects beyond the background level of phenomena observed in darkness. Synchronized cells exposed to white light, but not to gold light, showed dramatic increases in mutants resistant to 6-thioguanine or to ouabain. The mutagenic risk to humans from usual doses of white fluorescent light is very small compared with normal mutagenic exposures received every day from the sun, and cell cultures should be shielded from daylight. (16 refs)

79-0398 Photodestruction of Pheomelanin: Role of Oxygen. (Eng) Chedekel, M. R. (Dept. Chemistry, Ohio State Univ., Columbus, OH, 43210); Smith, S. K.; Post, P. W.; Pokora, A.; Vessell, D. L. *Proc Natl Acad Sci USA* 75(11): 5395-5399; 1978.

The mechanism of the photodestruction of pheomelanin (PHM), a chromophore-protein complex from human skin and hair, was investigated. PHM was isolated from red human hair samples and subjected to photolysis under various conditions in the presence and absence of oxygen, Rose Bengal, superoxide dismutase (SD), nitroblue tetrazolium (NBT), and hydrogen peroxide. When irradiated by UV light of wavelengths longer than 300 nanometers, PHM rapidly lost color in a manner dependent upon pH and the initial concentrations of pigment and oxygen. Amino acid composi-

tion remained constant, indicating the apparent destruction of the chromophore. Photoreaction also took place in the absence of oxygen, but at a much slower rate. Photodestruction was accelerated by the singlet oxygen sensitizer Rose Bengal, and the conversion of NBT to diformazan during the photolysis of oxygenated PHM was consistent with a superoxide reaction, this conversion being quenched by the presence of SD. Hydroxyl radical produced by the dismutation of superoxide is suggested to be the primary chromophore-attacking species. These results are consistent with the involvement of superoxide in the aerobic photolysis of pheomelanin and suggest a mechanism for UV-induced cell damage in redheaded people. (40 refs)

VIRAL CARCINOGENESIS

- 79-0399** Specific Site of Action for Single-strand Specific Nuclease on the Double-stranded Circular DNA Intermediates of an Avian RNA Tumor Virus. (Eng) Hsu, T. W. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111); Guntaka, R. V.; Taylor, J. M. *J Virol* 28(3): 1015-1017; 1978.

The action of the single-strand specific nuclease, S1, of *Aspergillus oryzae* on circular viral DNA intermediates obtained from the quail tumor line, QT6, at 1 day after infection was studied. S1 alone made one cut in the circles. If the circles were digested first with S1 and then with restriction endonuclease *Hpa* I, the major fragments obtained (3.25, 3.01, and 1.53 megadaltons) were indistinguishable from those obtained with *Hpa* I in the absence of S1. The specific cut with S1 did not occur if the circles were first converted to a linear form with restriction endonuclease *Kpn* I and then digested with the S1 nuclease. Also, the S1 site on the relaxed circular species was not identical to the site(s) at which the circle was nicked to become relaxed. The location of the S1 site on the circles was the same for the PrC strain of avian sarcoma virus as for the B77 strain. It is estimated that the site was in the vicinity of the tRNA (trp) primer binding site, which is immediately adjacent to but not part of the 0.21-megadalton sequence redundancy of large circular intermediates. (10 refs)

- 79-0400** Analysis of Unintegrated Avian RNA Tumor Virus Double-Stranded DNA Intermediates. (Eng) Hsu, T. W. (Inst. Cancer Res. Fox Chase Center, Philadelphia, PA, 19111); Sabran, J. L.; Mark, G. E.; Guntaka, R. V.; Taylor, J. M. *J Virol* 28(3): 810-818; 1978.

The unintegrated double-stranded avian sarcoma virus DNA intermediates that were previously detected in quail QT-6 cells at 1 day after infection were characterized. The data suggested that the unintegrated linear viral DNA intermediates synthesized in infected QT-6 cells are 0.5 ± 0.3 megadaltons (Md) larger than expected for a hypothetical unit-length double-stranded transcript of the viral RNA, excluding polyadenylic acid (A). Relative to the map restriction enzyme sites on viral DNA synthesized in vitro, the additional sequences on the in vivo-synthesized DNA seem to be located at the left end of the map and seem to represent a direct terminal redundancy of sequences located at the right side. The data also indicate that the circular DNA intermediates in the infected cells are heterogeneous in size. There are two predominant species of circle, one being about 0.21 ± 0.3 Md larger than the other. The unit-length nondefective DNA has been identified as having a mass of 5.85 Md. (24 refs)

- 79-0401** Viral Adenosine Triphosphatase. (Eng) Banerjee, R. K. (Indian Inst. Experimental Medicine,

4, Raja S.C. Mullick Rd., Calcutta-32, India). *Experientia* 34(11): 1430-1432; 1978.

The catalytic and immunological properties of an adenosine triphosphatase (ATPase) from avian myeloblastosis virus (AMV), Rous virus, and Reo virus were compared. AMV was found to hold ATPase in a conformation that induces high enzyme activity. The catalytic and antigenic properties of the Rous and AMV viruses were similar, but those of the Reo virus were significantly different. (9 refs)

- 79-0402** Primary Avian Tendon Cells in Culture: An Improved System for Understanding Malignant Transformation. (Eng) Schwarz, R. I. (Lab. Chemical Biodynamics, Lawrence Berkeley Lab., Univ. California, Berkeley, CA, 94720); Farson, D. A.; Soo, W. J.; Bissell, M. J. *J Cell Biol* 79(3): 672-679; 1978.

The in vitro transformation of highly differentiated primary avian tendon (PAT) cells by Rous sarcoma virus (RSV) was investigated. The PAT cells were grown in F12 medium with 0.2% fetal calf serum and 50 μ G/ml ascorbate. By the accepted criteria of morphologic alteration, increased rate of 2-deoxyglucose uptake, and loss of density-dependent growth control, PAT cells transformed as well as did less-differentiated chick embryo fibroblasts. The percentage of collagen produced by PAT cells following transformation by RSV decreased from 23% to 2.5%. This decrease is a function of transformation, not just of virus replication, since cells infected with a transformation-defective mutant synthesized the normal percentage of collagen. Normal PAT cells responded to the addition of ascorbate to the medium by increasing collagen synthesis from 8% to 23%. Transformed PAT cells, however, were insensitive to ascorbate, producing collagen at a level of 2.5%, with or without ascorbate addition. The normal cells also exhibited increased collagen synthesis in response to an increase in cell density, while transformed cells did not. These findings indicate that the distinctions between the normal differentiated state and the transformed state are magnified in PAT cells so that several of the virus-induced changes are easier to study. The results suggest that the breakdown in the normal regulatory mechanisms that maintain the differentiated state is related to the phenomenon of malignant transformation. (26 refs)

- 79-0403** Induction of DNA Synthesis in Terminally Differentiated Myotubes by the Activation of the *src* Gene of Rous Sarcoma Virus. (Eng) Kobayashi, N. (Dept. Microbiology, Sch. Medicine, Univ. Pennsylvania, Phila-

delphia, PA, 19104); Kaji, A. *Proc Natl Acad Sci USA* 75(11): 5501-5505; 1978.

An attempt was made to induce DNA synthesis in terminally differentiated myotubes by activating the *src* gene of Rous sarcoma virus (RSV). Mononucleated myogenic cells from 11-day-old SPAFAS chicken embryos were infected with tsLA24 or tsNY68, temperature-sensitive transformation mutants of RSV. The infected cells were then incubated at the nonpermissive temperature (41 C) and allowed to develop into multinucleated myotubes. These myotubes have withdrawn from the cell cycle, and no DNA synthesis was observed as long as the cultures were maintained at 41 C. However, when the incubation temperature was lowered to the permissive temperature (36 C) for expression of the *src* gene, DNA synthesis was induced in multinucleated myotubes. For this induction to occur, cells infected with tsLA24 had to be incubated at 36 C for at least 50 hr; cells infected with tsNY68, however, required <20 hr incubation at 36 C. Induction of DNA synthesis was observed by autoradiography as well as by measuring incorporation of ³H-thymidine into the macromolecular fraction in these myotube cultures. The constant presence of the *src* gene product is necessary for maintaining the capacity of the myotubes to induce DNA synthesis because when the temperature was returned to 41 C, this capacity was lost. During DNA induction, one biochemical marker of muscle (creatine kinase) remained unchanged. (39 refs)

- 79-0404 Immunofluorescent Detection of RNA-Dependent DNA Polymerase (Reverse Transcriptase) in XC Cells.** (Rus) Karmysheva, V. Ia. (Inst. Poliomyelitis and Virus Encephalitis, Moscow Oblast', USSR); Graevskaia, N. A.; Ivanov, A. P.; Sushko, L. N. *Dokl Akad Nauk SSSR* 242(4): 942-945; 1978.

The indirect immunofluorescent assay was employed for detection of RNA-dependent-DNA-polymerase (reverse transcriptase) in rat XC cells transformed by Rous sarcoma virus. Incubation of a cell culture with rabbit antisera against purified reverse transcriptase from avian myeloblastosis virus resulted in specific fluorescence, which was indicative of the presence of avian reverse transcriptase in the genome of XC cells. - 79-0405 Chromosome Aberration in Human Neoplasm: Occurrence and Significance (Meeting Abstract).** (Eng) Levan, G. (Inst. Genetics, Univ. Gothenburg, Gothenburg, Sweden); Mitelman, F. *Clin Genet* 14(5): 300; 1978. (no refs)

- 79-0406 Comparison of the Expression of the *src* Gene of Rous Sarcoma Virus In Vitro and In Vivo.**

(Eng) Sefton, B. M. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); Beemon, K.; Hunter, T. *J Virol* 28(3): 957-971; 1978.

The *src* gene of several strains of Rous sarcoma virus (RSV) was translated in vitro from heat-denatured 70S virion RNA in a nuclease-treated reticulocyte lysate, and the polypeptide products were compared with those present in chick cells transformed by these viruses. The in vitro translation resulted in the synthesis of several related polypeptides ranging from 17,000 to 60,000 daltons in size. When sera from tumor-bearing rats injected at birth with the Schmidt-Ruppin RSV (SR-RSV) were used for immunoprecipitation of the products of the in vitro translation of RNA from SR-RSV subgroups A and B and Prague RSV subgroup C, all but the 17,000-dalton polypeptide precipitated. The 60,000-dalton (60K) polypeptides precipitated from chick cells transformed by these viruses were essentially identical to the corresponding 60K polypeptides produced in vitro, although some strain-specific differences were evident. The precipitates from the transformed cells also contained two other polypeptides (one of 80,000 and one of approx 52,000 daltons) that were not obviously analogous to polypeptides synthesized in vitro. None of the precipitates from transformed cells contained polypeptides analogous to the 33K and 25K *src*-related in vitro products. (18 refs)

- 79-0407 Nucleotide Sequence Relationships Between the Genomes of an Endogenous and an Exogenous Avian Tumor Virus.** (Eng) Coffin, J. M. (Dept. Molecular Biology and Microbiology, Tufts Univ. Sch. Medicine, Boston, MA, 02111); Champion, M.; Chabot, F. *J Virol* 28(3): 972-991; 1978.

Oligonucleotide mapping combined with nucleic acid hybridization was used to examine and compare the genomes of Rous-associated virus-O (TRAV-O), an endogenous virus of chickens, and the Prague strain Rous sarcoma virus, subgroup B (Pr-RSV-B), an exogenous sarcoma virus. ³²P-labeled 70S RNA from each virus was digested with RNase T₁ and fingerprinted by two-dimensional gel electrophoresis which showed that the two virus genomes share large regions of identical or very similar sequence. The 5'-terminal half of the genomes (corresponding to the *gag* and *pol* regions) is virtually identical, sharing 10/13 mapped common oligonucleotides. This region is followed by a region comprising 25%-30% of the genome (the *env* region), which contains substantial nucleotide sequence differences, most or all of which are due to single base changes as judged by the results of hybridization-competition experiments combined with fingerprinting. To the 3' side of the *env* region, the RAV-O genome contains a very short sequence not found in Pr-RSV-B, whereas the Pr-RSV-B genome contains a much longer unrelated sequence. The central portion of this sequence comprises the *src* gene. The RAV-O genome does not contain any nucleotide sequence related to the "c region" found very near the 3' end of all exogenous tumor viruses.

These results imply a role for both recombination and point mutation selection events in the evolution of avian tumor virus genomes. (49 refs)

- 79-0408 Further Study on the Three-Dimensional Structure of the Core of Herpesvirus (Meeting Abstract).** (Eng) Okada, K. (Dept. Comp. Pathology, Hokkaido Univ., Sapporo, 060, Japan); Fujimoto, Y.; Nakanishi, Y. H. *J Electron Microsc* (Tokyo) 27(4): 389; 1978. (no refs)

- 79-0409 Demonstration of Mouse Mammary Tumour Virus (MuMTV) Antigenicity in Human Milk by Means of Immunodiffusion Technique.** (Eng) Zotter, S. (Institut für Pathologie, Medizinischen Akademie "Carl Gustav Carus", Fetscherstrasse 74, DDR-8019 Dresden, E. Germany); Kemmer, C.; Lossnitzer, A. *Exp Pathol (Jena)* 16(1-6): 180-185; 1978.

The micro-Ouchterlony immunodiffusion technique was used to detect mouse mammary tumor virus (MMTV) antigenicity in the 1.26- to 1.28- μ g/ml sucrose density gradient fraction of pooled human milk that had been treated with detergents and ether. The cross-reacting antigen(s) was precipitated by rabbit antisera to MMTV B particles prepared from murine milk and intracytoplasmic A particles isolated from MMT tissue. No detectable MMTV antigen(s) was seen in milk samples that had not been treated with detergent and ether. The antigen(s) seemed to be identical with the main antigenic components of murine A and B particles. Electron microscopic investigation of the human milk "core" fraction revealed abundant characteristic granular structures 40-70 nanometers in diameter that often occurred as aggregations. It is not known whether the particulate structures are indeed subviral cores and whether they are associated with the MMTV antigenicity detectable in human milk. (35 refs)

- 79-0410 Passive Immunization of Newborn RIII Mice with Antiserum to Murine Mammary Tumor Virus: Effect on Virus Expression and on Incidence of Mammary Tumors Later in Life (Meeting Abstract).** (Eng) Wald, A. (Tel Aviv Univ., Tel Aviv, Israel); Frensdorff, A. *Isr J Med Sci* 15(2): 194-195; 1979. (no refs)

- 79-0411 Naturally Occurring Humoral Immunity to Murine Mammary Tumor Virus (MuMTV) and MuMTV gp52 in Mice with Low Mammary Tumor Incidence.** (Eng) Arthur, L. O. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Fine, D. L. *Int J Cancer* 22(6): 734-740; 1978.

Antibodies to murine mammary tumor virus (MuMTV) were

found in sera from male and female mice by a radiolabeled intact MuMTV precipitation assay. These antibodies were demonstrated in strains of mice that have a high incidence of mammary tumors and transmit the highly oncogenic MuMTV via the milk (C3H) and in mice that have been foster-nursed to remove the highly oncogenic milk-borne MuMTV (C3Hf) and subsequently have a decreased mammary tumor incidence. Antibodies to MuMTV were readily demonstrated in C3H mice at 6 wk of age, whereas only marginal antibody activity was detected in C3Hf mice < 15 wk of age. Antibody levels increased the age in both strains, but in C3Hf mice the immune response was also accelerated by pregnancy. Several feral and BALB/c NIV mouse sera with high 125 I-MMTV precipitating titers also precipitated the major MuMTV envelope glycoprotein (gp52). Max precipitation of the 125 I-gp52 was > 50% with a 20% endpoint binding titer of 1:40, whereas the same sera precipitated > 80% of 125 I-MMTV with a titer of > 1:2,560. These naturally occurring antibodies were specific for gp52, since only MuMTV and purified MuMTV gp52 competed for binding of radiolabelled antigens by limiting dilutions of mouse sera. MuMTV gp52 was found in both C3H and C3Hf mice, predominantly in organs that had secretory functions, such as submaxillary glands and mammary tissue of females and submaxillary, coagulating, and vesicular glands and vas deferens of males. Extracts of other tissues were negative for MuMTV gp52. Neither gp52 nor naturally occurring antibodies for MuMTV were found in BALB/c or C57BL/6 mice. (32 refs)

- 79-0412 Mammary Tumor Virus Expression in the GR Mouse Strain: Efficiency of Chromosomal and Extrachromosomal Transmission.** (Eng) Imai, S. (Dept. Pathology, Nara Medical Univ., 840 Shijo-cho, Kashihara, Nara-ken 634, Japan); Hilgers, J.; Van Nie, R.; Verstraeten, R. *Gann* 69(5): 607-611; 1978.

Mammary tumor virus (MTV) antigen expression was determined by three different techniques in milk and secondary male genital organs of mice from segregating populations between GR and BALB/c mice: immunodiffusion tests, immunofluorescence absorption tests, and radioimmunoassay. One gene, *Mtv-2*, controls the expression of high levels of MTV antigen, as seen by the immunodiffusion test of milk and the immunofluorescence absorption test in epididymis, prostate, and coagulating glands. With the more sensitive radioimmunoassay, MTV antigens are also found in the absence of *Mtv-2*, which may be due to extrachromosomal transmission and a second gene, unlinked to *Mtv-2*. (26 refs)

- 79-0413 Strain-related Variation in the Interaction of Ferritin-conjugated Plant Lectins with Mouse Mammary Tumor Viruses.** (Eng) Hixson, D. C. (Res. Div., Univ. Texas System Cancer Center, Smithville, TX, 78957); Bowen, J. M.; Ohtsuki, Y.; Scanlon, M.; Dmochowski, L. *Cancer Res* 39(1): 199-206; 1979.

Ferritin-conjugated plant lectins of different saccharide specificities were used to characterize oligosaccharides present on the surface of mouse mammary tumor virus (MMTV) produced in mammary tumor cells from C3H/He/Tex, A/Dm, and RIII/Dm mice. A ferritin conjugate of wheat germ agglutinin specific for 2-acetamido-2-deoxy-D-glucopyranosyl residues (Fer-WGA) did not label C3H/He/Tex MMTV, whereas budding, immature, and mature forms of RIII/Dm MMTV and immature and mature forms of A/Dm MMTV were labeled; budding forms of A/Dm MMTV were partially labeled. C3H/He/Tex and A/Dm MMTV were labeled by a ferritin conjugate of concanavalin A specific for alpha-D-gluco- and alpha-D-mannopyranosyl residues, whereas RIII/Dm MMTV was only partially labeled. All MMTV's were labeled by a ferritin conjugate of *Ricinus communis* agglutinin I specific for D-galactopyranosyl residues. There was a dense, uniform distribution of Fer-WGA on all three strains of MMTV cells. No major antigenic differences were detected among the three strains of MMTV. The results suggest the existence of strain-related variations in MMTV envelope oligosaccharide determinants, and they indicate that virus-specific oligosaccharide determinants are present in cellular plasma membranes in the early stages of virus assembly. (25 refs)

- 79-0414 Detection of Mouse Mammary Tumor Virus RNA in BALB/c Tumor Cell Lines of Nonviral Etiologies.** (Eng) Dudley, J. P. (Dept. Microbiology, Univ. California Sch. Medicine, San Francisco, CA, 94143); Butel, J. S.; Socher, S. H.; Rosen, J. M. *J Virol* 28(3): 743-752; 1978.

A complementary DNA (cDNA) probe to mouse mammary tumor virus (MMTV) RNA was synthesized using calf thymus DNA oligonucleotides as a random primer. This probe was then used to study the expression of MMTV RNA in cell lines from BALB/c tumors induced in vivo either spontaneously or in response to viral, chemical, or hormonal stimuli. The cDNA had a length of approx 400-500 nucleotides and specifically hybridized to MMTV RNA and BALB/c lactating mammary gland RNA, but not to Moloney leukemia virus RNA. Calf thymus DNA-primed cDNA could protect 50% of iodinated MMTV RNA from S1 nuclease digestion at cDNA-RNA ratios of 1:1 and 90% of labeled viral RNA at ratios of 10:1. Thermal denaturation of MMTV RNA-cDNA hybrids yielded a T_m of 88.5 C, indicative of a well-base-paired duplex. Screening of mouse mammary tumor cells from MMTV sequences revealed that 3/5 lines of BALB/c origin had undetectable levels of viral RNA (<3 molecules/cell) by RNA excess hybridization. Two of the three "virus-negative" cell lines were derived from tumors induced by 7,12-dimethylbenz(a)anthracene, whereas the third tumor occurred spontaneously. Two lines from tumors induced by either viral (mammary tumor virus) or hormonal (17- β -estradiol) stimulus contained between three and nine molecules of MMTV RNA per cell by both RNA excess and cDNA excess hybridization. Clonal derivatives of these

tumor lines had levels of viral RNA comparable to those of their parental lines. Therefore, it appears that the presence of detectable MMTV RNA sequences is not a necessary requirement for the maintenance of all murine mammary gland neoplasias. (35 refs)

- 79-0415 Isolation of Host-Range Variants of Mouse Mammary Tumor Viruses That Efficiently Infect Cells In Vitro.** (Eng) Howard, D. K. (Lab. Viral Carcinogenesis, NCI, NIH, Building 37, Room 1B19, Bethesda, MD, 20014); Schlom, J. *Proc Natl Acad Sci USA* 75(11): 5718-5722; 1978.

Host-range variants of the highly oncogenic mouse mammary tumor virus (MMTV) of RIII, C3H, and GR mice were isolated. These variants have the ability to productively infect cells in vitro with high efficiency (at multiplicities of infection ≤ 1) and with extremely short latent periods to the production of de novo virus (within 4 days after infection). The variants were obtained by serial virus passage in feline cells. The resultant variant stocks reacted in group-specific radioimmunoassays for the MMTV major external glycoprotein (gp52) and major internal protein (p28), possess a protein profile similar to that of wild-type MMTV, and contain a virion-associated DNA polymerase with a magnesium cation preference. Addition of dexamethasone and insulin to culture media enhanced the titer of de novo MMTV to levels of approx 10^{10} particles per 75-cm² flask (containing 5×10^6 cells) per 24 hr. Variant stocks exhibited no evidence of contamination with either murine or feline C-type retroviruses. MMTV variants derived from C3H and RIII mice exhibited differential host ranges that included the ability to productively infect feline, canine, bat, mink, murine, and human cells. These MMTV host-range variants will facilitate study of the complete replicative cycle of MMTV and elucidate the interaction of MMTV with various hormones, physical or chemical carcinogens, and tumor promoters in the initiation and promotion of mammary neoplasia. - 79-0417 Specificity of Cell Surface Virus Receptors on Radiation Leukemia Virus and Radiation-induced Thymic Lymphomas.** (Eng) McGrath, M. S. (Lab. Experimental Oncology, Dept. Pathology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Decleve, A.; Lieberman,

M.; Kaplan, H. S.; Weissman, I. L. *J Virol* 28(3): 819-827; 1978.

The fluorescence-activated cell sorter was used to quantitate the binding of fluorescent C57BL/Ka retrovirus isolates to mouse lymphoid cells. The binding to fluoresceinated or rhodaminated murine leukemia virus (MuLV) to target cells showed saturation kinetics and was blocked by homologous MuLV; bound MuLV had a polypeptide profile identical to that of input MuLV. Thymic lymphomas bound specifically the MuLV that induced them, whereas only 0.5% to 2% of normal thymocytes showed equivalent MuLV binding. Simultaneous binding of excess fluoresceinated radiation leukemia virus (RadLV) and rhodaminated MCF-247 AKR virus to RadLV-induced and spontaneous AKR thymic lymphomas indicated that each lymphoma possessed receptors that could distinguish and preferentially bind the inducing virus. RadLV-induced thymic lymphomas bound only thymotropic-leukemogenic RadLV and not eco- or xenofibrotropic MuLVs. Thus, virus binding in this system involves only leukemogenic isolates of these retroviruses, implying a central role of this receptor-ligand interaction in the processes of leukemic transformation. 79-0422 Infectious Murine Leukemia Virus from DNA of Virus-negative AKR Mouse Embryo Cells. (Eng) Lowy, D. R. (Dermatology Branch, NCI, NIH, Bethesda, MD, 20014). *Proc Natl Acad Sci USA* 75(11): 5539-5543; 1978.

The infectivity of AKR DNA was determined in experiments in which (1) the AKR cells from which the transfecting DNA was isolated or (2) the NIH 3T3 cells onto which the transfecting DNA was inoculated were treated with 20 or 100 µg/ml 5-iododeoxyuridine (IUdR). DNA from virus-negative AKR mouse embryo cells was infectious for NIH 3T3 cells if the transfected cells were treated with IUdR 24 hr before and/or after addition of the DNA. The virus isolated after transfection of the AKR DNA was an ecotropic murine leukemia virus (MuLV) indistinguishable from endogenous AKR MuLV. The AKR DNA was not infectious in the absence of IUdR treatment of the recipient cells. DNA from AKR cells treated with IUdR before DNA was not infectious unless the recipient cells had been treated with IUdR. Transfected DNA from NIH mouse cells was not infectious even when the recipient cells had been treated with IUdR. DNA from cells chronically infected with AKR MuLV or Rauscher MuLV was infectious with or without IUdR treatment of the recipient cells, but the infectivity was not enhanced by IUdR. The results indicate that the endogenous AKR MuLV DNA genome is potentially infectious. The data are consistent with an IUdR-sensitive restriction in the recipient NIH 3T3 cells that prevents viral replication from endogenous AKR MuLV DNA but does not prevent viral replication from MuLV DNA of productively infected cells. 79-0425 Characterization of Rauscher Murine Leukemia Virus Envelope Glycoprotein Receptor in

Membranes from Murine Fibroblasts. (Eng) Kalyanaraman, V. S. (Dept. Cell Biology, Litton Bionetics, Inc., Bethesda, MD, 20014); Sarngadharan, M. G.; Gallo, R. C. *J Virol* 28(3): 686-696; 1978.

The nature of the murine cell-surface receptor for Rauscher murine leukemia virus (R-MuLV) was analyzed. Plasma membrane preparations from KA31 (mouse) cells contained receptors for the binding of the R-MuLV envelope glycoprotein gp70. This binding was demonstrated by gel filtration of a mixture of the microsomal fraction of the cells and ¹²⁵I-labeled gp70. A rapid and convenient assay was developed to measure the complex formation between the membrane receptors and gp70. It involved specific precipitation of the complex by 3% to 4% polyethylene glycol. Complex formation was responsive to the concentrations of both the receptor and gp70 and also to changes in temperature and pH. gp70 binding was a noncooperative, saturable process, and an association constant of $3.5 \times 10^8 \text{ M}^{-1}$ was estimated from the binding data. The complex formation was reversible, and a near-total exchange of ¹²⁵I-labeled gp70 in the complex was achieved by incubation with excess unlabeled gp70. Complex formation was inhibited by protein-denaturing agents, guanidine hydrochloride, and urea. Pretreatment of the membrane fractions with chymotrypsin or phospholipase C led to a loss of the membrane-associated receptor activity, indicating that a lipoprotein structure was important for receptor function, consistent with the observation that non-ionic detergents strongly inhibit complex formation. (32 refs)

79-0426 Tryptic Peptide Analyses of Polypeptides Generated by Premature Termination of Cell-free Protein Synthesis Allow a Determination of the Rauscher Leukemia Virus *gag* Gene Order. (Eng) Murphy, E. C. (Biology Dept., Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Arlinghaus, R. B. *J Virol* 28(3): 929-935; 1978.

Polypeptides thought to be fragments of the Rauscher murine leukemia virus (R-MuLV) *gag* precursor (Pr65*gag*) were studied by tryptic peptide analysis and the results were used to determine the R-MuLV *gag* gene order. Translation of R-MuLV 35S RNA in an mRNA-dependent cell-free protein-synthesizing system yielded polypeptides identical to authentic Pr65*gag* and *gag-pol* precursor (Pr200*gag-pol*) as well as premature termination fragments of mol wt 40,000, 33,000, 28,000 (which migrated as a doublet at 27,000 and 28,000 mol wt in polyacrylamide gels), and 18,000 (designated P40*gag*, P33*gag*, P27/28*gag*, and P18*gag*, respectively). The tryptic maps of these premature termination polypeptides were compared with that of full-size Pr65*gag*. The data indicated that in comparison with Pr65*gag*, P40*gag* was missing all of protein p10 and part of protein p30, placing p10 at the C terminus of Pr65*gag* and p30 next to it. Both P33*gag* and P27/28*gag* appeared to contain all of protein p15 and protein p12 but progressively lesser amounts of p30. In comparison with p27/28*gag*, P18*gag* had lost the p12 tryptic pep-

tide. The results suggest that the R-MuLV *gag* gene order is NH₂-p15-p12-p30-p10-COOH. (18 refs)

79-0427 Changes in Splenic Cell Size Distribution During Murine Viral Leukemogenesis (Meeting Abstract). (Eng) Meredith, R. F. (Cancer Res. Unit, Allegheny General Hosp., Pittsburgh, PA, 15212); Campagna, E. D.; Mager, J. G.; O'Kunewick, J. P. *Cell Tissue Kinet* 11(6): 685; 1978. (no refs)

79-0428 Low-Multiplicity Infection of Moloney Murine Leukemia Virus in Mouse Cells: Effect on Number of Viral DNA Copies and Virus Production in Producer Cells. (Eng) Fan, H. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); Jaenisch, R.; MacIsaac, P. *J Virol* 28(3): 802-809; 1978.

NIH-3T3 and SV-T2 mouse cells infected with Moloney murine leukemia virus (M-MuLV) were cloned using two different methods, and the number of M-MuLV-specific DNA copies per infected cell was determined. The number of M-MuLV-specific DNA copies detected varied from one to eight per infected cell in different lines. All cultures prepared by the multiple cycle of infection method had more than two copies of M-MuLV per diploid cell equivalent, whereas 8 of the 13 cultures prepared by the low multiplicity of infection method had less than two copies per diploid cell equivalent. However, some of the latter cultures contained as much or more viral DNA than did cultures prepared by the former method. A strict gene-dosage effect on virus production was not observed, indicating that other regulatory mechanisms affecting the amount of virus production must exist. The data indicate that infection at low multiplicity followed by cloning of individual cells before virus spread has occurred can result in infected cells that contain only one copy of M-MuLV-specific DNA. 79-0431 The Influence of α -Fetoprotein on Moloney Sarcoma Virus Oncogenesis: Evidence for Generation of Antigen Nonspecific Suppressor T Cells. (Eng) Gershwin, M. E. (Section Rheumatology-Clinical Immunology, Univ. California Sch. Medicine, Davis, CA); Castles, J. J.; Ahmed, A.; Makishima, R. *J Immunol* 161(6): 2292-2298; 1978.

A study was made of the effect of murine α -fetoprotein (AFP) on the threshold dose, mean tumor size, regression time, and number of progressors for Moloney sarcoma virus (MSV)-induced tumors in BALB/c mice. AFP-treated mice (200 μ g ip) developed larger tumors, required a longer period for regression, and had a significantly higher mortality than murine albumin treated mice (200 μ g ip). Furthermore, AFP, but not murine albumin or transferrin, allowed tumor growth when normally subthreshold doses of virus were injected. These effects of AFP could be removed by pretreatment and precipitation of AFP by anti-AFP; on the other hand, they were not altered by dialysis and were noted at serum levels of approx 170 to 440 μ g/ml. The heightened susceptibility of AFP-treated mice to MSV appears to be due to the generation of a cortisone- and radiation-sensitive splenic, and not lymph node, suppressor T cell. Indeed, the suppression produced by AFP was antigen-nonspecific and could be demonstrated in unmanipulated mice after transfer of spleen cells from AFP-treated donors. This transfer of suppression was noted in the IgG and IgA secondary responses to sheep RBC as well as by quantitating the response of T cell mitogens on spleen cells. These data suggest that AFP, in pharmacologic doses, alters a subpopulation of spleen cells to exhibit suppressive function or that AFP is involved in differential homing patterns of lymphoid cells. The relationships of AFP and immune competence appear to be broad. (36 refs)

79-0432 Retinoids Block Phenotypic Cell Transformation Produced by Sarcoma Growth Factor. (Eng) Todaro, G. J. (NCI, NIH, Bethesda, MD, 20014); De Larco, J. E.; Sporn, M. B. *Nature* 276(5685): 272-274; 1978.

The effects of retinoids on sarcoma growth factor (SGF)-induced transformation and growth of rat fibroblast cells (NRK) in culture were studied. Retinyl acetate (6 nanograms/ml) inhibited the transforming effect and almost abolished the growth-stimulatory effect of SGF but did not affect normal growth properties. Neither retinyl acetate nor retinoic acid reversed the phenotype of virally transformed cells nor blocked cell transformation produced by the Moloney strain of mouse sarcoma virus (MSV) or simian virus 40. Retinoids prevented SGF-induced colony formation in soft agar but did not inhibit the growth of MSV-transformed mouse and rat cells in soft agar. The data suggest that endoge-

nous growth promoters may be significant factors in naturally occurring cancers and that suppressors of transformation offer a potential approach to preventing the expression of the transformed phenotype. (26 refs)

79-0435 Complement and Tumor Antibody Levels in Cats, and Changes Associated with Natural Feline Leukemia Virus Infection and Malignant Disease. (Eng) Grant, C. K. (Dept. Microbiology, Harvard Sch. Public Health, Boston, MA, 02115); Pickard, D. K.; Ramaika, C.; Madewell, B. R.; Essex, M. *Cancer Res* 39(1): 75-81; 1979.

Lytic complement and complement-dependent antibody (CDA) levels were measured in 314 normal and feline leukemia virus (FeLV)-infected cats. None of 11 specific-pathogen-free (SPF) cats showed evidence of FeLV infection or CDA in the blood, and of 191 non-SPF cats that were negative for FeLV infection, 99 were also negative for CDA. Greatly depleted complement levels were detected only in cats that were FeLV- or CDA-positive. Of 15 laboratory cats bled periodically, CDA titers tended toward a slight loss of activity with time in the 9 that remained free of FeLV infection; CDA activity showed a minor cycling effect in the 6 animals that were persistently viremic. Complement levels remained relatively constant in the FeLV-negative animals, but fluctuated considerably in the FeLV-positive cats. Severely depleted complement levels were sometimes associated with FeLV-related anemia or lymphoid cancers. The data suggest that CDA may protect cats from developing FeLV-related leukemias or lymphomas. It is possible that some lymphoid tumors in cats develop and progress in the face of a CDA-mediated tumor immune response at times when complement levels are depleted. (36 refs)

79-0436 Surface Antibodies of Human Myelogenous Leukaemia Leukocytes Reactive with Specific Type-C Viral Reverse Transcriptases. (Eng) Jacquemin, P. C. (Lab. Tumor Cell Biology, NCI, NIH, Bethesda, MD, 20014); Saxinger, C.; Gallo, R. C. *Nature* 276(5685): 230-236; 1978.

An attempt was made to determine whether antibodies (ab's) to specific reverse transcriptases (RT's) from certain mammalian C-type oncornaviruses can be identified in humans. Purified IgG from acute myelogenous leukemia (AML), chronic myelogenous leukemia (CML) or normal blood WBC was tested for inhibition of various viral RT's. Purified IgG from the CML patients in blast crisis (CML-BC) specifically neutralized RT from feline leukemia virus, but purified IgG from the AML patients and from normal subjects were less reactive and, in some cases, preferentially reacted with the RT from horizontally transmitted primate C-type viruses. This indicates the presence of a heterogeneous immune response to RT or to an RT-like molecule in humans. Evidence that the inhibitor of RT in eluates from some human WBC is a specific ab and that the reaction is an antigen-ab interaction includes the biochemical and physical properties of the most reactive fraction, the specificity of the inhibition of polymerization reactions, the removal of known nonspecific inhibitors of these reactions, and assays based on factors other than inhibition of enzyme activity. The presence of an ab with relatively high activity and specificity to FeLV RT in CML-BC and the absence of IgG with similar anti-RT specificity in the chronic phase and remission of CML and in randomly selected normal blood samples might help in detecting early blast transformation in this disease. Similarly, the preferred reactivity of the IgG from AML WBC against RT from simian sarcoma virus and the preferred reactivity of the IgG from normal blood WBC against RT from gibbon ape leukemia virus may be useful in following patients in remission and in preleukemic states. (49 refs)

- 79-0437 Effect of RNA Tumor Virus-specific Protein p30 on Reverse Transcriptase. Intraspecies and Interspecies Interaction Between Reverse Transcriptase and p30.** (Eng) Bandyopadhyay, A. K. (Lab. Molecular Biology, Baltimore Cancer Res. Center, NCI, NIH, Baltimore, MD, 21201); Levy, C. C. *J Biol Chem* 253(22): 8285-8290; 1978.

The intra- and interspecies interaction between the reverse transcriptase (RT) and p30 purified from various retroviruses was examined. RT and p30 from feline leukemia virus, simian sarcoma virus, endogenous rat virus, and rhabdomyosarcoma virus formed multiprotein complexes between both intra- and interspecific sources. Intraspecific complexes stimulated the incorporation of ³H-thymidine monophosphate into (dT)₁₂(rA)_n several times over that produced by RT alone. Interspecific complexes also increased incorporation, but to a lesser extent. The molar ratios of p30:RT necessary for max enzyme activity were 30-35:1 for autologous proteins, 40-60:1 for heterologous proteins. The sedimentation rate value of the intraspecies complexes varied between 12S and 16S, and Sepharose gel filtration indicated that the mol wt of these complexes was approx 400,000; values for the interspecies complexes were 18S and 600,000. KCl dissociated all complexes into individual RT and p30 components, although the concentration required was much lower for the interspecies complexes (0.3 vs 0.8 M KCl). Competition studies in which an

interspecies complex was exposed to p30 autologous to the RT within the complex resulted in displacement of the heterologous (p30) protein and the formation of a new intraspecific complex. (22 refs)

- 79-0438 Bovine Leukosis: Investigation of Risk for Man.** (Eng) Olson, C. (Dept. Veterinary Science, Univ. Wisconsin, Madison, WI, 53706); Driscoll, D. M. *J Am Vet Med Assoc* 173(11): 1470-1472; 1978.

To evaluate previous comparative studies that failed to show a positive correlation between human and bovine leukosis and to evaluate the risk of bovine leukosis virus (BLV) infection for man, an attempt was made to detect antigens of BLV in human peripheral blood lymphocytes cultured from the blood samples of 50 volunteers with varying degrees of exposure to BLV and to cattle. Blood samples underwent analysis by fluorescent antibody tests, immunodiffusion (ID), and single radial ID tests. Results revealed that all 50 volunteers were negative for antibody to both p23 and glycoprotein BLV antigens. Since it appears that human beings probably exposed to BLV do not develop detectable antibodies to the virus, it is concluded that there is no relation between bovine leukosis and human leukemia. Although a possible association between these entities was indicated by a few preliminary studies, strong statistical evidence supports the hypothesis that BLV is not oncogenic for humans. (24 refs)

- 79-0439 Epidermodysplasia Verruciformis: Viral Particles in Early Malignant Lesions.** (Eng) Yabe, Y. (Dept. Virology, Cancer Inst., Okayama Univ. Medical Sch., Okayama 700, Japan); Yasui, M.; Yoshino, N.; Fujiwara, T.; Ohkuma, N.; Nohara, N. *J Invest Dermatol* 71(4): 225-228; 1978.

The lesions in two patients with Epidermodysplasia verruciformis (EV) were examined histologically and by electron microscopy. Four of the lesions showed the benign histologic appearance typical of EV. In all four lesions viral particles which appeared to belong to the papova group were observed. These particles were generally found in the cell nuclei and frequently showed crystalline arrangements. Virus particles resembling the virus of common human warts were also found in these lesions. A fifth lesion appeared histologically to be in an early stage of malignant transformation (intraepidermal epithelioma) and a sixth appeared to be in a more advanced stage of transformation (early invasive squamous cell carcinoma). Viral particles of the same size and morphology as those found in the benign lesions were found in these lesions also, but the number of particles per cell was less than in the benign lesions. The results suggest that at least some of the virus-induced lesions of EV actually become malignant. (17 refs)

- 79-0440 Extent of Transcription of the E Strand of Polyoma Virus DNA During the Early Phase**

of Productive Infection. (Eng) Acheson, N. H. (Dept. Virology, Swiss Inst. Experimental Cancer Res., 1066 Epalinges, Switzerland); Mieville, F. *J Virol* 28(3): 885-894; 1978.

The extent of transcription of the E strand of polyoma virus DNA during early infection was determined by a method in which the relative rate of synthesis of RNA from coding and noncoding regions of the E strand could be measured directly. Early polyoma virus-specific RNA, in nuclei and cytoplasm of mouse kidney cells pulse-labeled with ³H-uridine, was analyzed by hybridization with filter-bound *Hpa*II fragments of polyoma DNA. About 40% of labeled cytoplasmic virus-specific RNA hybridized with *Hpa*II fragment 2, which represents about 40% of the region coding for E-strand messenger RNA's (mRNA's); <5% hybridized with fragments 1 or 3, which lie outside this region. About 30% of labeled nuclear virus-specific RNA hybridized with fragment 2, and a small but significant fraction (7% to 14%) hybridized with fragments 1 and 3. About two-thirds of the nuclear RNA that hybridized to fragment 1 was complementary to the E strand, and one-third was complementary to the L strand. Results did not vary greatly in samples labeled for 15 min to 3 hr. The major species of pulse-labeled nuclear polyoma-specific RNA sedimented at 22S and thus is slightly larger than the 19S cytoplasmic mRNA. These results show that approx 75% of early nuclear RNA is transcribed from the region of the E strand, which codes for early mRNA's, and that there is probably a site at which transcription is terminated at the end of this region. However, approx 15% of early nuclear RNA is transcribed from the remainder of the E strand, perhaps by readthrough of this termination signal. In addition, there is a small amount of transcription from the L strand, whose significance is unclear. Neither the L-strand transcripts nor the nonmessenger E-strand transcripts are transported to the cytoplasm. (40 refs)

- 79-0441 Sequences from the Genome of a Non-transforming Mutant of Polyoma Virus. (Eng) Soeda, E. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2, England); Griffin, B. E. *Nature* 276(5685): 294-298; 1978.

The region of the polyoma virus DNA that probably determines the nontransforming phenotype of *hr-t* mutant NG-18 was sequenced and compared with wild-type polyoma virus DNA. NG-18 was previously shown to have a deletion of about 3% that mapped at 80-85 units on the physical map of wild-type polyoma virus DNA. The present study indicated that the fifth largest *Hinf* I restriction endonuclease fragment in polyoma DNA contained the NG-18 deletion. Except for this deletion, the mutant and wild-type DNA's were indistinguishable over this region, suggesting that the deletion is responsible for the mutant phenotype. Any protein(s) induced by the mutant would likely be smaller than might be expected from a consideration of the size of the deletion alone, and a protein from NG-18 would probably lack most of the cysteines contained in the translation product from

wild-type DNA. The region of the DNA covered by the deletion is probably not a coding region for large tumor (T) antigen. However, the sequences that lie between 80.5 and 84 units on the physical map of polyoma virus DNA probably code for a part of small t antigen and may also code for the membrane-associated protein reported for polyoma virus. Both small t antigen and this protein may have a role in transformation. (29 refs)

- 79-0442 BK and Herpes Simplex Virus Antibodies in Renal Cell Carcinoma. (Eng) Pyrhonen, S. (Lab. Viral Immunopathology, Dept. Virology, Univ. Helsinki, Haartmaninkatu 3, SF-00290 Helsinki 29, Finland); Manttyjarvi, R.; Tykka, H.; Sarna, S.; Tallberg, T. *Med Biol* 56(4): 194-200; 1978.

The relationship between serum antibodies against BK virus (BKV) and postoperative clinical course was studied in 76 renal cell carcinoma patients. BKV antibodies and antibodies against seven control viruses were determined by the hemagglutination-inhibition or complement-fixation technique. BKV and herpes simplex virus (HSV), but no other virus antibodies, showed a clear correlation with the clinical course of the renal carcinomas. The patients without BKV antibodies or with marginal antibody titers (≤ 10) had a significantly longer observed expectation (OE) of life (44.1 mo) than the patients with BKV antibody titers ≥ 20 (26.7 mo). Similarly, patients with low or undetectable HSV antibodies (titer ≤ 8) also had a significantly longer OE of life (54.0 mo) than the rest of the patients (32.7 mo). The results suggest that BKV and HSV have an as yet undefined relationship to renal cell carcinomas. (39 refs)

79-0450 Membrane Fusion as a Mechanism of Simian Virus 40 Entry into Different Cellular Compartments. (Eng) Maul, G. G. (Wistar Inst. Anatomy and Biology, Philadelphia, PA, 19104); Rovera, G.; Vorbrodt, A.; Abramczuk, J. *J Virol* 28(3): 936-944; 1978.

To investigate the possible ways that the simian virus 40 (SV40) particle could pass into the nuclear compartment, permissive (CV1 green monkey kidney) and nonpermissive (mouse embryo) SV40-infected cells were analyzed ultrastructurally. Viral particles were found in the cytoplasm, rough endoplasmic reticulum, nuclear envelope, lysosomes, and mitochondria. Upon entering the cell, the virion obtained a tight membrane envelope. It seemed to be either released from the envelope upon fusion with other membranes of the cell or aggregated into tubular membrane specializations upon fusion with other membrane-enveloped particles. Reconstructed morphological sequences and the finding of SV40 in different spaces of the cell suggest that entry of SV40 into the different compartments and eventually into the replication site was facilitated by its capacity for being enveloped by a variety of membranes (notably, the cell membrane and the nuclear membrane) and the sequential fusion and fission of these membranes. (16 refs)

79-0451 Characterization of the Amino-Terminal Tryptic Peptide of Simian Virus 40 Small-t and

Large-T Antigens. (Eng) Mellor, A. (Translation Lab., Imperial Cancer Res. Fund, London WC2A 3PX, England); Smith, A. E. *J Virol* 28(3): 992-996; 1978.

The amino-terminal tryptic peptide of both forms of simian virus 40 (SV40) tumor antigen (small t and large T) were identified. Small-t and large-T antigen were synthesized in vitro and labeled with methionine donated by initiator transfer RNA. Tryptic peptide fingerprinting was used to identify the amino-terminal peptide of the two proteins. Similar fingerprint analysis of small t and large T made in vitro in the absence of acetyl coenzyme A showed that the mobility of the amino-terminal peptide was changed under these conditions and suggested that the peptide is acetylated. These data establish that the amino-terminal methionine residue of SV40 small t and large T results from an initiation event, not post-translational cleavage, and provides additional evidence that the amino terminus of both proteins is acetylated. The identification of the amino-terminal peptide provides a useful marker for further studies of different forms of T antigen from cells infected with and transformed by SV40 and related viruses. (19 refs)

79-0452 Transcription Pattern of In Vivo-Labeled Late Simian Virus 40 RNA: Equimolar Transcription Beyond the mRNA 3' Terminus. (Eng) Ford, J. P. (Rockefeller Univ., New York, NY, 10021); Hsu, M. T. *J Virol* 28(3): 795-801; 1978.

The pattern of RNA transcription on the late (L) DNA strand late in the simian virus 40 (SV40) infectious cycle was examined by separating pulse-labeled RNA chains according to size and hybridizing them to an ordered series of DNA fragments obtained by restriction enzyme digestion. The data suggested that there is a single major RNA species transcribed from the late DNA strand. The RNA transcript has its 5' end a short distance counterclockwise to map coordinate 0.735 and is synthesized in a clockwise fashion with equimolar transcription for at least 1,000 nucleotides past the 3' terminus of the mRNA at map coordinate 0.175. The largest RNA transcripts are terminated in the region between coordinates 0.43 and 0.655, or 1,300 to 2,400 nucleotides beyond the 3' end of the mRNA at coordinate 0.175. (21 refs)

79-0453 5-Bromodeoxyuridine and Mutagenic Effect of Oncornavirus SV40. (Rus) Varshaver, N. B. (Inst. Molecular Genetics, Moscow, USSR); Gorbunova, L. V.; Lukash, L. L.; Shapiro, N. I. *Dokl Akad Nauk SSSR* 242(3): 707-710; 1978.

To test the hypothesis that the agents that have a synergistic effect with oncornavirus SV40 with respect to cell transformation also show synergism with respect to mutagenesis, the auxotrophic mutant strain of Chinese hamster cells (237-8 glu-ts) was incubated with bromodeoxyuridine (BDU: 10 µg/ml for 48 hr) and were then infected with SV40

(strain 128). To estimate the incidence of reverse mutants, cells were inoculated into minimal medium. The incidence of reverse mutations after combined exposure to SV40 and BDU ranged from 26.1×10^{-6} to 62.7×10^{-6} (in different experiments), compared with $0.54-1.65 \times 10^{-6}$ after exposure to SV40 alone and $13.0-20.9 \times 10^{-6}$ after exposure to BDU alone. 79-0456 Characterization and Biogenesis of Nuclear Simian Virus 40 RNA (Meeting Abstract). (Eng) Horowitz, M. (Weizmann Inst. Science, Rehovot, Israel); Laub, O.; Bratosin, S.; Reuveni, Y.; Aloni, Y. *Isr J Med Sci* 15(1): 100; 1979. (no refs)

79-0457 Proteins Bound to Heterogeneous Nuclear RNA of Simian-Virus-40-infected Cells. (Eng) Pagoulatos, G. N. (Departement de Biologie Molculaire, Institut Pasteur, 25/28 Rue de Docteur-Roux, F-75724 Paris-Cedex-15, France); Yaniv, M. *Eur J Biochem* 91(1): 1-10; 1978.

The protein patterns in normal and simian virus 40 (SV40)-infected monkey kidney cells were compared. Heterogeneous nuclear RNA-protein (hnRNA-protein) complexes from SV40-infected cells late in infection contained 7%-10% RNA sequences specific to SV40 DNA; these complexes sedimented at 60S-70S. The proteins and RNA of hnRNA followed a parallel pattern in metrizamide gradients and gave a peak with the same mean density of 1.28 g/cm^3 . Two-dimensional gel electrophoresis showed four proteins in the SV40-infected cells that were not present in the normal cells. One of these proteins corresponded to the major capsid protein VP1 of SV40. The other three proteins observed only in the infected cells appeared to be cellular proteins induced by the virus infection. Thus, these proteins are good candidates for specific hnRNA-bound proteins of SV40 nuclear RNA. Actin, which was identified in both normal and infected cells, may have a role in RNA-protein packaging and transport to the cytoplasm. (29 refs)

79-0458 Human Antibodies Reactive with Purified Envelope Antigens of Primate Type C Tumor Viruses. (Eng) Kurth, R. (Friedrich Miescher Lab., Max-Planck-Insts., Spemannstrasse 37-39, 7400 Tubingen, W. Germany); Mikschy, U. *Proc Natl Acad Sci USA* 75(11): 5692-5696; 1978.

Human sera from healthy individuals, previously shown to react with viral antigens in preparations of detergent-disrupted simian C-type viruses, were tested against virus polypeptides purified to homogeneity. Populations of human antibodies reacted with highly purified envelope glycoproteins of the simian sarcoma virus-simian sarcoma-associated virus complex (gp70) and the Friend leukemia virus complex (gp71). Several immunological parameters influencing human antibody binding to C-type tumor virus antigens were characterized. These parameters indicated that human antibodies tend to bind to what is probably a subset of the antigenic determinants on the virus envelope antigens and that different human sera recognize the same antigenic determinants on the virus envelope antigens tested. The possible origin of these antibodies is discussed. (53 refs)

79-0459 Studies on the DNA-Excision Repair in Lymphocytes of Patients with Recurrent Herpes Simplex. (Eng) Fanta, D. (2nd Dept. Dermatology, Ludwig Boltzmann-Institut, Infektiöse venero-dermatologische Erkrankungen, Vienna, Austria); Topaloglou, A.; Altmann, H. *Bull Cancer (Paris)* 65(3): 341-346; 1978.

DNA repair was investigated in lymphocytes from 21 patients with recurrent herpes simplex infections and in 5 healthy controls. The patients (ages 8-82), who were free of other forms of chronic disease, were examined during symptom-free intervals. Semiconservative DNA synthesis was measured by ^3H -thymidine ($10 \mu\text{Ci/ml}$) labeling, the proportion of suppressed DNA synthesis was determined in a hydroxyurea assay, and UV-induced and gamma-radiation-induced DNA repair synthesis was measured by ^3H -thymidine incorporation. The semiconservative DNA synthesis of patients was significantly below control values. Although DNA synthesis activity 30 min after UV exposure was above that of controls, suggesting vigorously progressing repair synthesis, rates were reduced 90 min post-exposure, implying early repair termination. The distributions of DNA synthesis values below those of controls following gamma irradiation showed the persistence of chain breaks caused by this radiation. In four patients studied, the autoradiographic labeling index as well as the av number of grains present were markedly reduced in unscheduled (repair) DNA synthesis. Therefore, herpes simplex interferes with DNA repair mechanisms and increases the risk of late effects in patients with recurrent herpes manifestations. (37 refs)

79-0460 Antibodies to Herpes Simplex Virus Types 1 and 2 in Patients with Squamous-Cell Car-

cinoma of Uterine Cervix in India. (Eng) Seth, P. (Dept. Microbiology, All-India Inst. Medical Sciences, Ansari Nagar, New Delhi-110016, India); Prakash, S. S.; Ghosh, D. *Int J Cancer* 22(6): 708-714; 1978.

The indirect hemagglutination test (IHA) was used to study the occurrence of antibodies to herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2) in 124 women with squamous cell carcinoma of the uterine cervix, 46 with noncervical cancer, and 116 matched normal controls. Type-specific antibody titers were determined by the IHA inhibition test. A significantly larger proportion of cervical cancer (CC) patients (64.5%) had HSV-2 antibody activity than either the other cancer patients (38%) or controls (36.2%), but there was no difference in the proportions positive for HSV-1 activity. Mean antibody titers to HSV-1 as well as HSV-2 were significantly higher in the CC patients than in the other two groups. However, measurement of type-specific antibodies was of no help in establishing past infection by HSV-2 in CC patients, as no type-specific HSV-2 antibodies were produced in 58%. There were no significant differences in the incidence of HSV-2 antibodies or in HSV-1 or HSV-2 mean antibody titers among the different clinical stages and histological types of CC. The data suggest that HSV-2 may be causally associated with squamous cell CC, but not as a passenger virus of carcinomatous tissue. Further differentiation of this tissue may be a host-controlled mechanism. (26 refs)

79-0461 Quantitative Correlation of Morphological Alterations of the Nucleus with Functional Events During In Vitro Infection of Glial Cells with Herpes Simplex Homini (HSV 2). (Eng) Dupuy-Coin, A. M. (Laboratoire de Pathologie Cellulaire, Institut Biomedical des Cordeliers, 21, Rue de l'Ecole de Medecine, 75270 Paris Cedex 06, France); Arnoult, J.; Bouteille, M. *J Ultrastruct Res* 65(1): 60-72; 1978.

Changes in the ultrastructure of nuclei of cultured human glial cells were examined at various times after viral infection with herpes simplex hominis type 2 (HSV2). Glial cells grown from a biopsy of normal nervous tissue were infected after five passages using HSV2 at a titer of 5×10^5 plaque-forming units/ml. Samples were taken at 3, 5, 6, 8, 14, and 24 hr for electron microscopic examination. The most striking feature of herpes-infected nuclei was the migration of the chromatin toward the nuclear periphery. Nucleolar changes occurred early and soon led to complete nucleolar destruction. At later times, only fibrillar masses surrounding the fibrillar centers could be found. The number of perichromatin granules increased to a considerable extent so that they appeared as closely packed clusters. The number of nuclear bodies decreased with infection time and completely disappeared within 24 hr. Viral nucleocapsids began to appear as early as 8 hr after infection in some cells. These observations combined with previously published data point to the perichromatin granules as the morphological substrates of the viral premessenger RNA. These findings also support the hypothesis that

the protein of nuclear bodies is related to viral proteins. The disappearance of the nuclear bodies as the number of nucleocapsids increases in the nucleus suggests that the protein of the nuclear bodies is used to form the nucleocapsids. (62 refs)

79-0462 Effect of Time and Diet on the Immune Status of Mice Challenged with Herpes-transformed Cells. (Eng) Gridley, D. S. (Loma Linda Univ., Loma Linda, CA, 92354). *Diss Abstr Int* B 39(5): 2139-2140; 1978. (no refs)

79-0463 Long-Term T-Cell-mediated Immunity to Epstein-Barr Virus in Man. I. Complete Regression of Virus-induced Transformation in Cultures of Seropositive Donor Leukocytes. (Eng) Moss, D. J. (Queensland Inst. Medical Res., Bramston Terrace, Brisbane, Queensland 4006, Australia); Rickinson, A. B.; Pope, J. H. *Int J Cancer* 22(6): 662-668; 1978.

A previous observation that adult WBC exposed to potent Epstein-Barr virus (EBV) preparations and cultured at a concentration of 10^6 cells/ml frequently failed to give rise to cell lines if subculture was delayed beyond the first week postinfection was investigated further. Peripheral blood mononuclear cells from donors of known serological status with respect to EBV were exposed to the virus in vitro and then cultured at concentrations of 10^6 or 2.5×10^5 cells/ml. All cultures from nine seronegative adult and 12 fetal donors gave rise to cell lines following subculture 4 wk postinfection. In contrast, seropositive donor cultures seeded at the higher cell concentration developed foci of proliferating EB nuclear antigen-positive cells within the first 1-2 wk but thereafter regressed completely, and subcultures made after 4 wk never gave rise to cell lines. Out of 18 seropositive donors tested, 15 showed regression in all cultures seeded at $\geq 10^6$ cells/ml; with the other three donors, a proportion of replicate cultures regressed. T-cell depletion and reconstitution experiments showed that the effect was absolutely dependent upon the presence in the cultures of T cells from these seropositive donors. The results strongly suggest that the regression phenomenon is an in vitro expression of long-term T-cell-mediated immunity to EBV that most, if not all, infected individuals possess. (25 refs)

79-0464 Seroconversion Against Epstein-Barr Virus in Two Nonhuman Primate Species Infected by the Oropharyngeal Route. (Eng) Glaser, R. (Dept. Medical Microbiology, Ohio State Univ. Sch. Medicine, 333 W. Tenth Ave., Columbus, OH, 43210); Lee, K. J.; Lang, C. M.; Levy, B. *J Infect Dis* 138(5): 695-698; 1978.

The pathogenicity of Epstein-Barr virus (EBV) was investigated in two nonhuman primate species inoculated oro-

pharyngeally. Eight squirrel monkeys were inoculated with EBV by spraying the virus into the nose and throat. Three monkeys were used as mock-infected controls. Serum samples were obtained approx 1 mo apart and analyzed for EBV-specific antibodies (ab's). None of the monkeys seroconverted. The last samples assayed were obtained 113 days after inoculation. The animals were then reinoculated. Sera from all reinfected animals remained negative for at least 104 days after the second inoculation; after that, two monkeys seroconverted, as demonstrated by the presence of ab's to early antigen (EA) and viral capsid antigen (VCA) at 125 days. Both animals lacked ab to EB nuclear antigen (EBNA). By day 166, however, ab to EA disappeared and the titer of ab to VCA decreased. By day 197, both animals were negative. At 197 days, a third monkey had ab to EBNA at a titer of 1:32; no ab to EA or VCA was detected. A possible explanation is given for this unusual ab response. In another experiment, one cotton-ear and two cotton-topped marmosets were inoculated directly into the nasopharyngeal tissue with EBV. One of the cotton-topped marmosets seroconverted 82 days after inoculation, with an ab titer to EA of 1:64 and VCA of 1:256; no ab to EBNA was found. None of the monkeys and marmosets developed disease. (10 refs)

- 79-0465 Somatic Cell Hybrids Between Human Lymphoma Cell Lines. V. IdUrd Inducibility and P3HR-1 Superinfectability of Daudi/HeLa (DAD) and Daudi/P3HR-1 (DIP-1) Cell Lines.** (Eng) Moar, M. H. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Ber, R.; Klein, G.; Westman, A.; Eriksson, I. *Int J Cancer* 22(6): 669-674; 1978.

Two types of somatic cell hybrids were used in iododeoxyuridine (IdUrd) induction and Epstein-Barr virus (EBV) superinfection studies aimed at further elucidating the regulation of the EBV cycle. The first cell line, DIP-1, a hybrid formed between two human lymphoma EBV producers (Daudi and P3HR-1), contained EBV DNA, expressed the virus-determined nuclear antigen (EBNA), and produced two EBV-associated antigens: early antigen (EA) and viral capsid antigen (VCA). The second cell line, DAD, a hybrid series of clones formed between Daudi and a HeLa cell derivative (D98), differed with regard to the expression of EBNA, EA, VCA, and the content of EBV DNA. EA was regularly induced in the EBV DNA-containing hybrids following IdUrd treatment. This induction was greater in lines spontaneously expressing EA. In two hybrids, DIP-1 and DAD10, VCA and viral DNA synthesis were also induced in the presence of IdUrd, the latter being detected by in situ hybridization with P3HR-1 EBV complementary RNA. DIP-1 was superinfectable by the P3HR-1 EBV strain, whereas the DAD series of hybrids were refractory to P3HR-1 superinfection and lacked EBV receptors. (25 refs)

- 79-0466 Genomic Stability of Gibbon Oncornavirus.** (Eng) Sun, L. (Comparative Oncology Lab.,

Univ. California-Davis, Davis, CA, 95616); Kawakami, T. G.; Matoba, S. I. *J Virol* 28(3): 767-771; 1978.

The 70S RNAs from several gibbon type C viruses were examined for sequence homology by molecular hybridization using complementary DNA probes. All virus isolates shared partial homology in their 70S RNA. However, using any of the complementary DNA (cDNA) probes, the degree of genomic homology varied, indicating that each virus was a distinct substrain. A myelogenous leukemia virus (GaLV-3M) was serially passaged through three unrelated gibbons that sequentially developed the same disease. The genomic homology remained unchanged after the three passages, having greater than 93% homology based on cDNA-70S RNA hybridization and melting temperature analysis of the duplex. The genome from another isolate (SEATO GaLV) was similarly found to be unchanged after the virus was naturally transmitted in gibbons. The genomic variation in the isolates was not therefore, the consequence of recent horizontal transmission from a common virus. It is possible that gibbons in their natural habitat are carriers of SEATO GaLV. (21 refs)

- 79-0467 Antigenic Characterization of a New Gibbon Ape Leukemia Virus Isolate: Seroepidemiologic Assessment of an Outbreak of Gibbon Leukemia.** (Eng) Krakower, J. M. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD, 20014); Tronick, S. R.; Gallagher, R. E.; Gallo, R. C.; Aaronson, S. A. *Int J Cancer* 22(6): 715-720; 1978.

A C-type virus recently isolated from a leukemic gibbon ape in a colony located on Hall's Island, Bermuda, was characterized with respect to the antigenic properties of its *gag* and *env* gene-coded proteins. This virus, designated GaLV-H, was found to be closely related immunologically to C-type viruses previously isolated from gibbons (GaLV-SF, GaLV-SEATO, GaLV-Br) and from woolly monkeys (simian sarcoma-associated virus). However, GaLV-H was readily differentiated from these isolates in a radioimmunoassay for its *env* gene product, gp70. Seroepidemiology established that GaLV-H was horizontally transmitted among gibbons within the colony. There was no evidence of exposure leading to an immune response to the virus or of viral antigenemia in humans working in association with these animals. (29 refs)

- 79-0468 Virus Detected in Cells Explanted into Tissue Culture from Naturally Occurring Malignant Lymphoma in Rhesus Monkeys.** (Eng) Manning, J. S. (Dept. Bacteriology, Univ. California, Davis, CA, 95616); Griesemer, R. A. *Curr Microbiol* 1(3): 157-162; 1978.

To determine if there might be a common viral etiology to the outbreak of 43 cases of spontaneous lymphoma in one macaque colony within 4 yr, neoplastic lymphoid tissue from 10 rhesus monkeys were explanted into tissue cultures, and the cells were subsequently examined for virus expression by

thin-section electron microscopy. The presence of adenovirus, reovirus, foamy virus, and herpesviruslike (*Herpes simiae*?) nucleoids was revealed. When cell-free filtrates from cultures containing the latter three viruses were added to cultures of normal virus-free rhesus lung cells, a cytopathic effect was produced. Virus particles typical of the explant culture could be demonstrated in infected indicator cells. C-type RNA tumor virus particles were not observed electron microscopically in any of the lymphoma tissues or lymphoma cell cultures examined. It is not known if any of the viruses detected played a role in the etiology of the lymphomas. (31 refs)

- 79-0469 In Vitro RNA-RNA Splicing in Adenovirus 2 mRNA Formation.** (Eng) Blanchard, J. M. (Rockefeller Univ., New York, NY, 10021); Weber, J.; Jelinek, W.; Darnell, J. E. *Proc Natl Acad Sci USA* 75(11): 5344-5348; 1978.

The in vitro conversion of an adenovirus 2 (Ad2) nuclear messenger RNA (mRNA) precursor to a molecule with the size and sequence composition of mature mRNA is described. "Splicing" of the precursor to an Ad mRNA was accomplished in isolated cell-free extracts. Hypotonically swollen HeLa cells were labeled for 10 min with ³H-uridine, and the nuclei were isolated. Addition of "cytoplasmic" extract was required for the reaction to occur. However, because this extract was prepared by swelling cells in hypotonic buffer and stripping the cytoplasm during homogenization, it is likely that some enzyme or cofactor leaked from the nuclei during this preparation. The nuclear precursor, a poly(A)-terminated RNA molecule approx 5 kilo-bases (kb) long, contained sequences complementary to the 58.5-75.9 region of the Ad2 genome, including sequences spliced out of the mature mRNA molecule. The in vitro-spliced product was a poly(A)-terminated RNA molecule identical in size to the cytoplasmic 72,000-mol wt protein mRNA (2 kb long) in which the sequences encoded in the 70.7-75.9 region of the viral genome were spliced to those encoded at 58.7-65.6, with the sequences encoded at 66.1-70.7 deleted. It is concluded that RNA-RNA splicing of parts of a nuclear precursor RNA molecule is probably a general mechanism in mRNA manufacture in higher cells. (39 refs)

- 79-0470 Characterization of a Variant of Human Adenovirus Type 2 Which Multiplies Efficiently in Simian Cells.** (Eng) Klessig, D. F. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Hassell, J. A. *J Virol* 28(3): 945-956; 1978.

H2hr400 (abbreviated to hr400), a variant of human adenovirus 2 (Ad2) that grows in simian cells without the help of simian virus 40 (SV40) or simian adenoviruses, was characterized. Genome analysis set an upper limit of 73 base pairs (bp) to the amount of SV40 information that hr400 could

contain. Late viral proteins were synthesized in permissive human cells infected with Ad2, hr400, or Ad2 plus SV40 and in simian cells infected with hr400 or Ad2 plus SV40; these proteins were dramatically reduced in simian cells infected with Ad2 alone. Both the hr400 and the Ad2+ND1 30K protein were able to act in *trans*. The data exclude the possibility that SV40 sequences are present in hr400, allowing it to multiply in simian cells. Using a modified marker rescue technique, the mutation in hr400 was mapped between coordinates 59 and 80 of the viral genome. A point mutation may be responsible for the new phenotype in hr400. (39 refs)

- 79-0471 Genetic Analysis of Adenovirus Type 2. VIII. Physical Locations of Temperature-sensitive Mutations.** (Eng) Hassell, J. A. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Weber, J. *J Virol* 28(3): 671-678; 1978.

When 44 wild-type recombinants (*ts*+) viruses obtained in crosses between 4 temperature-sensitive (*ts*) adenovirus type 5 (Ad5) and 4 *ts* Ad2 mutants were analyzed by cleavage with 4 restriction endonucleases (*EcoRI*, *HindIII*, *SmaI*, and *BamHI*), 36 of the recombinants contained both Ad2 and Ad5 sequences. The physical map positions of five Ad2 and Ad5 *ts* mutations were determined: the Ad2 *ts1* mutation mapped near position 59 between positions 57 and 69; Ad2 and *ts3* mapped between 44 and 57 on the physical map; Ad2 *ts4* mapped between 30 and 43; Ad2 *ts48* mapped between 69 and 80; and Ad5 *ts1* mapped between 69 and 71. (37 refs)

- 79-0472 Transcription of the Transforming Region of Adenovirus Type 5 in a Rat Cell Line Transformed by a Small Restriction Fragment.** (Eng) Chinnadurai, G. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, St. Louis, MO, 63110); Fujinaga, K.; Rho, M. H.; van der Eb, A. J.; Green, M. *J Virol* 28(3): 1011-1014; 1978.

The fraction of the adenovirus type 5 genome expressed as messenger RNA (mRNA) in a rat cell line, 5RK, transformed by the *HsuI*-G restriction fragment was analyzed by saturation hybridization using separated strands of the ³²P-labeled *HindIII*-G fragment. Between 45% and 50% of the G fragment (about 8 x 10⁵ daltons) was expressed as mRNA. The size of the polyadenylic acid-terminated virus-specific cytoplasmic and nuclear RNA was determined by electrophoresis on polyacrylamide gels containing 98% formamide, followed by hybridization of the gel slices with viral DNA. The major virus-specific RNA species present in the cytoplasm was approx 14S, whereas the major virus-specific RNA present in the nucleus was 30S-32S. The large size of the nuclear virus-specific RNA suggests that the host sequences are covalently linked to the viral transcript. (17 refs)

- 79-0473 Role of DNA Polymerase γ in Adenovirus DNA Replication.** (Eng) van der Vliet, P. C. (Lab. Physiological Chemistry, State Univ. Utrecht, Vondellaan 24 A, 3521 GG Utrecht, Netherlands); Kwant, M. M. *Nature* 276(5687): 532-534; 1978.

The cellular DNA polymerase required for adenovirus (Ad) DNA replication was determined by incubating nuclei from Ad2- or Ad5-infected KB cells with the ingredients necessary for in vitro DNA synthesis and various concentrations of 2',3'-dideoxythymidine triphosphate (ddTTP), which inhibits DNA polymerase γ and β , but not DNA polymerase α or, in similar conditions, cellular DNA or simian virus 40 (SV40) DNA synthesis. Nuclear Ad DNA synthesis was very sensitive to ddTTP, with 50% inhibition occurring at a ddTTP/dTTP ratio of 1.4×10^{-2} . Cellular DNA synthesis was not inhibited up to a ratio of 20. In African Green monkey kidney cells, Ad5 DNA synthesis was very sensitive to ddTTP, but SV40 DNA synthesis was only inhibited when ddTTP was present in at least 20-fold excess compared with dTTP. The inhibition of Ad DNA synthesis was independent of incubation time and could be suppressed by an excess of dTTP. The mechanism of inhibition can be explained by assuming that 2',3'-dideoxythymidine monophosphate is incorporated into growing DNA chains and acts as a chain terminator. DNA polymerases from the KB cells could be distinguished by their different sensitivity to ddTTP: the α form was most resistant (50% inhibition at a ddTTP/dTTP ratio of 30), the β form was partially resistant (50% inhibition at a ratio of 1), and the γ form was most sensitive. It is assumed that DNA polymerase γ is required for chain elongation of Ad replicative intermediates. DNA polymerase γ and mitochondrial DNA polymerase share identical properties, and both Ad DNA and mitochondrial DNA replicate unidirectionally according to a strand-displacement mechanism, in contrast to nuclear DNA synthesis or papovavirus DNA replication. There may be at least two enzymatically distinguishable replication mechanisms in mammalian cells. (19 refs)

- 79-0474 Enhancement of Viral Transformation for Evaluation of the Carcinogenic or Mutagenic Potential of Inorganic Metal Salts.** (Eng) Casto, B. C. (Bio-Labs, Inc., 2910 MacArthur Blvd., Northbrook, IL, 60062); Meyers, J.; DiPaolo, J. A. *Cancer Res* 39(1): 193-198; 1979.

Thirty-eight metal salts were tested for their capacity to enhance the transformation of Syrian hamster embryo cells by a simian adenovirus, SA7. All of the metal salts with known carcinogenic potential in animals or mutagenic activity in microbial or mammalian cells increased the SA7 transformation frequency. Metals were classified into three groups according to the concentration necessary to produce significant enhancement. Those showing highest activity (positive at < 0.05 mM) were the salts of antimony, arsenic, cadmium, chromium, and platinum. The second group (positive from 0.05 to 0.6 mM) included beryllium, cobalt, copper, lead, manganese, mercury, nickel, silver, thallium, and zinc. Iron salts were placed in a third group (only positive at concentrations > 0.9 mM). With the exception of $ZnCl_2$ and $ZnSO_4$, enhancement was demonstrated by both a relative increase in the viral transformation frequency and an absolute increase in the number of transformed foci among treated cells. The latter observation and the demonstration of enhancement in the absence of overt cell killing negate the possibility that enhancement resulted from the selection of transformation-sensitive cells. IMMUNOLOGY

- 79-0476 Serological Response to Intracaeal Injections of Antigenic Mouse Tumour Cells.** (Eng) Laursen, M. L. (Fibiger Lab., Ndr. Frihavnsgrde 70, DK-2100 Copenhagen O, Denmark). *Br J Cancer* 38(6): 692-698; 1978

Tumor-specific activity of sera from intracaeally immunized C3H mice was studied by the indirect membrane immunofluorescence technique. These sera apparently contained factors ("interfering factors") able to interfere with the binding of tumor-specific antibodies to antigenic sites on the tumor-cell membrane. These factors were specifically absorbed by the immunizing tumor cells, but they lacked determinants detectable by polyvalent fluorescein isothiocyanate (FITC)-conjugated goat anti-mouse gamma globulin. C3H/L1/a cells treated with a 1:4 dilution of positive-control serum after preincubation with enhancing serum at a dilution of 1:2 showed a higher fluorescent index than cells treated with enhancing serum alone, indicating either that not all antigenic sites were covered by factors in the enhancing serum, or that the interfering factors can be replaced by competing specific antibodies. The interfering phenomenon was only detectable when using serum from animals in which intestinal immunization was followed by enhanced growth of the challenging tumor. No interfering factors were detectable in serum from experiments in which inhibition of tumor growth followed the intestinal immunization. These observations indicate that enhancing serum contains factors with specificity and affinity for tumor-associated antigens, but that compared with the positive-control serum these factors lack certain immunoglobulin determinants. (27 refs)

- 79-0477 Increased Risk of Lymphoma in Sicca Syndrome.** (Eng) Kassan, S. S. (Section Clinical Immunology, Lab. Microbiology and Immunology, Natl. Inst. Dental Res., NIH, Bethesda, MD, 20014); Thomas, T. L.; Moutsopoulos, H. M.; Hoover, R.; Kimberly, R. P.; Budman, D. R.; Costa, J.; Decker, J. L.; Chused, T. M. *Ann Intern Med* 89(6): 888-892; 1978.

The case records of 136 women with sicca syndrome were analyzed to estimate the risk of lymphoma and to search for clinical features associated with its development during the course of the disease. The women were admitted to the National Institutes of Health (NIH) Clinical Center between 1954 and 1975. Seven patients developed non-Hodgkin's lymphoma from 6 mo to 13 yr after their first admission to NIH. This was 43.8 times ($p < 0.01$) the incidence expected from the rates of cancer prevailing among women of the same age range in the general population during this time. In addition, three cases of Waldenstrom's macroglobulinemia occurred in this study group. Eight patients developed cancers other than

lymphoma, similar to the number expected based on the rates prevailing in the general population. Patients with a history of parotid enlargement, splenomegaly, and lymphadenopathy had an increased risk of lymphoma. These clinical conditions did not appear to be early manifestations of undiagnosed lymphoma but rather seemed to identify a subgroup of patients with sicca syndrome with marked lymphoid reactivity, who had a particularly high risk of subsequently developing lymphoma. (36 refs)

- 79-0478 Pre-Morbid Factors in Hodgkin's Disease. II. BCG-Vaccination Status, Tuberculosis, Infectious Diseases, Tonsillectomy, and Appendectomy.** (Eng) Andersen, E. (Medical Dept. C., Gentofte Univ. Hosp., DK-2900 Hellerup, Denmark); Isager, H. *Scand J Haematol* 21(4): 273-277; 1978.

In young adults with Hodgkin's disease (HD), cell mediated immunity (CMI) was evaluated retrospectively from their health records. Sixty-three HD patients were compared with 182 controls matched for sex, age, and socioeconomic background. Information regarding BCG vaccinations, tuberculin skin tests, the frequency of tuberculosis, bacterial and viral diseases, and of tonsillectomy, adenoidectomy, and appendectomy was obtained from the school health records. Two of the Hodgkin's disease patients had had tuberculosis compared with none of the controls. No significant differences were found in the frequency of BCG vaccination, tuberculin reactivity, viral or bacterial diseases, adenoidectomy, tonsillectomy, or appendectomy. Neither complications to nor prolonged course of viral diseases were reported in HD patients or controls. These findings do not support a hypothesis of a pre-morbid CMI deficiency state in HD. They do not, however, exclude a disease-specific defect, which would not be disclosed by this study. (8 refs)

- 79-0479 An Immunodepressant Virus is Not Responsible for the Marked Tumorigenicity of the 13762A Mammary Adenocarcinoma in Syngeneic Fischer Rats (2 Letters to Editor).** (Eng) Huber, S. (Dept. Surgery, Stanford Univ. Medical Center, Stanford, CA, 94305); Lucas, Z. J.; Campbell, D. A.; Herberman, R. B. *Cell Immunol* 41(1): 207-210; 1978.

In view of previous findings (1) that an in vivo-maintained 13762 Fischer mammary adenocarcinoma line was contaminated with Kilham rat virus (KRV) and (2) that the isolated KRV, as well as 13762 tumor cells and cell-free tumor extracts, were cytopathic to lymphocytes and suppressed

in vitro lymphocyte responses to mitogens, allogeneic lymphocytes, and syngeneic tumor cells, the immune response to the 13762 mammary adenocarcinoma (obtained from the same source) was determined in syngeneic Fischer rats. The subline of the 13762A tumor studied was not cytopathic to lymphocytes and did not inhibit other parameters of immunologic activity. Observations on the host response to the tumor indicated that the tumor was immunogenic and was not contaminated with an immunodepressant virus. It appears that the answer to how the tumor circumvents host control in the face of an apparently normal cellular immune response lies in the interrelationships between the autoregulatory features of the immune response and the apparent ready shedding of this tumor's surface antigen. Different results obtained by different laboratories employing the same tumor system may be due to the influence of environment-induced dissimilarities in the tumor sublines. In a reply, it is stated that the above findings do not completely obviate the presence of KRV. (1) The stimulating cells used were not in vivo-passaged cells but were tissue culture-adapted monolayer cells carried within the sterile confines of an incubator. (2) In the first study, evidence for in vitro viral infection usually depended on high levels of cellular turnover, and levels of phytohemagglutinin (PHA) stimulation were higher (25-50,000 cpm) than those presented in the second study (10,000 cpm). (3) In the first study, evidence for viral inhibition depended on longer incubation times (3-5 days vs 2 days) in the PHA assay. A final conclusion should rest on a direct serological assay for the virus in ascites-passaged and tissue culture-adapted cells. (10 refs)

- 79-0480 Heterotransplantation of Human Glioma in Hereditary Asplenic-Athymic Mouse.** (Eng) Yamashita, M. (Neurological Inst., Kyushu Univ., Kyushu, Japan); Takeshita, I.; Kitamura, K. *Gann* 69(5): 735-736; 1978.

A study demonstrating the value of the Lasat mouse, a new strain with asplenia and athymia, in the study of heterotransplantation of human glioma is presented. All mice inoculated with 6×10^6 to 1×10^7 KNS-42 cells developed tumors showing histological and karyotypic features of the original tumor. (3 refs)

- 79-0481 Idiopathic Cardiomyopathy, Age, and Suppressor-Cell Dysfunction as Risk Determinants of Lymphoma after Cardiac Transplantation.** (Eng) Anderson, J. L. (Cardiology Div., Univ. Michigan Sch. Medicine, Ann Arbor, MI, 48109); Fowles, R. E.; Bieber, C. P.; Stinson, E. B. *Lancet* 2(8101): 1174-1177; 1978.

A review of lymphomas developing in recipients of cardiac allografts has yielded significant risk factors. Frequency varied strikingly according to original cardiac disease: lymphoma developed in 6/37 patients with prior idiopathic car-

diomyopathy (ICM) but in none of 54 patients with prior coronary-artery disease (CAD). All patients who developed lymphomas were aged under 40. Combination of both risk factors (ICM and age < 40) produced a subgroup with a highly significantly increased risk of lymphoma. ICM, but not CAD, was characterized by a defect in mitogen-induced mononuclear cell suppressor activity. It is postulated that defective regulation in the immune systems of younger patients under chronic alloantigen stimulation may allow lymphoid proliferation to proceed to lymphoreticular malignancy. Immunosuppressive agents such as azathioprine may exert a co-oncogenic effect. (19 refs)

- 79-0482 Primary Neoplastic Transformation In Vivo of Xenogeneic Skin Grafts on Nude Mice.** (Eng) Kreider, J. W. (Dept. Pathology, Specialized Cancer Res. Center, Coll. Medicine, Pennsylvania State Univ., Hershey, PA, 17033); Bartlett, G. L.; Sharkey, F. E. *Cancer Res* 39(1): 272-276; 1979.

The skin of New Zealand White rabbits was infected with Shope papilloma virus and grafted orthotopically to noninbred Swiss nude mice. Typical Shope rabbit papillomas developed in 11/12 grafts, but 8 similarly treated nude mouse skin grafts were not altered. These results demonstrate that the xenogeneic tissues retained their susceptibility to oncogenic agents after transplantation to nude mice. It should be feasible to study the carcinogenesis of human tissues in this system. (13 refs)

- 79-0483 Plasmacytoma Spleen Colonization: A Sensitive, Quantitative In Vivo Assay for Idiotypic-Specific Immune Suppression of MOPC-315.** (Eng) Daley, M. J. (Dept. Pathology, Immunobiology Labs., Univ. New Mexico Sch. Medicine, Albuquerque, NM, 87131); Bridges, S. H.; Lynch, R. G. *J Immunol Methods* 24(1/2): 47-56; 1978.

A spleen colony-forming assay that can detect the tumor-specific transplantation immunity directed to idiotype antigens in the surface membrane of MOPC-315 myeloma cells was developed. The assay measures those clonogenic cells of the myeloma that have a sufficient proliferative capacity to form macroscopic splenic foci within 14 days after iv challenge. BALB/c mice were inoculated iv with $4-8 \times 10^4$ viable spleen-passaged MOPC-315 (MOPC-315-s) cells prepared from myelomatous spleens. Fourteen days later, mice were anesthetized and sacrificed by cervical dislocation, and their spleens were removed and placed in vials containing Bouin's fixative. After 24 hr, the spleens were examined, and all visible and distinct nodules were counted. In normal BALB/c mice, there was a linear relationship between the number of MOPC-315 cells injected and the number of plasmacytoma colony-forming units (PCFU, spleen) observed within the range of 1-90 PCFU's per spleen. Idiotype-specific

myeloma graft resistance induced by immunization with the specifically purified dinitrophenol-binding IgA paraprotein of MOPC-315 could also be measured. The assay is highly quantitative, sensitive, reproducible, less time-consuming, and superior to conventional in vivo assays. The magnitude of resistance was apparently increased when systemic rather than local (sc) challenge was performed. One implication of a vigorous systemic idiotypic-specific resistance relates to the disseminated state that characterizes human idiotypic-bearing B-cell neoplasms such as myeloma and chronic lymphocytic leukemia when they are initially detected. (27 refs)

79-0484 Regulation of the Immune Response to Tumor Antigen. IV. Tumor Antigen-specific Suppressor Factor(s) Bear I-J Determinants and Induce Suppressor T Cells In Vivo. (Eng) Perry, L. L. (Dept. Pathology, Harvard Medical Sch., 25 Shattuck St., Boston, MA, 02115); Benacerraf, B.; Greene, M. I. *J Immunol* 121(6): 2144-2147; 1978.

The fine immunochemical specificity of the tumor-induced suppressor factor(s) and the mechanism by which it may operate in vivo were analyzed further. The suppressor factor(s) specific for the S1509a methylcholanthrene-induced fibrosarcoma was shown to bear determinants encoded by the I-J subregion of the murine major histocompatibility complex, since suppressive activity was removed by passage of the factor through an immunoadsorbent composed of anti-I-Jk coupled to Sepharose. No loss of activity was observed after passage of the factor through control columns composed of normal mouse globulin. Furthermore, activity could be recovered from the relevant immunoadsorbent by elution with high salt. The administration of crude suppressor factor(s) to normal animals for 4 days resulted in the development of a population of suppressor cells that acted in a manner analogous to the suppressor cell population used to produce the factor. These factor-induced suppressor cells were T cells, and they exhibited an antigen specificity similar to that displayed by the tumor-induced suppressor cells. Thus, the tumor-specific suppressor factor(s) bears I-J determinants and is capable of inducing the appearance of suppressor T cells in the non-tumor-bearing host. These cells may then act in a specific manner to limit host responsiveness to tumor antigen. (21 refs)

79-0485 Characteristic of Tumor-Associated Antigen in Chemically Induced Urinary Bladder Cancer of Rats. (Eng) Hashimoto, Y. (Dept. Hygienic Chemistry, Pharmaceutical Inst., Tohoku Univ., Aobayama, Aramaki, Sendai 980, Japan). In: *Gann Mongr Cancer Res* (21): 3-10; 1978.

The antigenic characteristics of seven bladder cancers induced in inbred ACI/N rats by N-butyl-N-(4-hydroxybutyl)-nitrosamine (BBN) were studied by different immunological methods. A common antigen was detected in three cancer

lines by an immunofluorescence test using anti-BC47 serum that was induced in allogeneic rats and absorbed with normal ACI rat cells. This common antigen was not related to tumor-specific transplantation antigen, which suggests that it is a tumor-associated antigen, although it may not act as an immunogen in the histocompatible host. By transplantation immunity in syngeneic rats, 2/6 cancer lines showed a high antigenicity, whereas the other four lines had low or undetectable antigenicity. The two highly antigenic cancers gave rise to cross resistance in immunized rats. However, this may not have been due to the existence of a common antigen in the cancers, since lymphoid cells from rats immunized with one cancer did not kill cancer cells of the other lines. (22 refs)

79-0486 Tumor-associated Antigens of Rat Moloney Sarcoma Cells. I. Cell-Surface Antigens. (Eng) Leung, K. (Dept. Immunopathology, Scripps Clinic and Res. Foundation, La Jolla, CA, 92037); Jones, J. M.; Feldman, J. D. *J Immunol* 121(5): 1836-1843; 1978.

The dissociated cell surface membranes of a rat Moloney sarcoma (MST), derived from a BN rat, were extracted with 2 M KI, with 6 M guanidine thiocyanate, or by papain digestion. Extracts obtained with these three reagents were fractionated on columns of controlled-pore glass (170 Å pore size). A fraction was eluted from each preparation that contained tumor-associated antigens (TAA), viral, fetal, and histocompatibility antigens. With an antibody specific for TAA, the TAA, devoid of detectable viral, fetal, and histocompatibility antigens, were coprecipitated by addition of goat antibody to rat immunoglobulin. After electrophoresis on slab gels, three bands were detected with estimated mol wts of 185,000, 150,000, and 70,000. These bands were not detected on slab gel electrophoresis with extracts of BC5, a chemically induced tumor (BC5), normal BN lymphoid cells, M-MuLV, or Moloney murine leukemia virus fetuses, after incubation with anti-TAA antibody and goat antibody to rat immunoglobulin. TAA extracts prepared with 2 M KI, 6 M guanidine thiocyanate, or papain digestion showed immunologic reactivity. Cold TAA inhibited the coprecipitation of labeled TAA by rat antibody specific for TAA; they elicited antibody in guinea pigs but not in rats; and antibodies specific for TAA were cytotoxic to MST in the presence of complement. (48 refs)

79-0487 Tumor-associated Antigens of Rat Moloney Sarcoma Cells. II. Cytosol Antigens. (Eng) Leung, K. (Dept. Immunopathology, Scripps Clinic and Res. Foundation, La Jolla, CA, 92037); Feldman, J. D. *J Immunol* 121(5): 1844-1848; 1978.

BN rat Moloney sarcoma cells (MST) were pulsed with ³⁵S-L-methionine for 10 and 60 min and lysed by vortexing in 0.5% deoxycholate, 0.5% NP₄₀, 0.02 M Tris, 0.04 M

NaCl, pH 7.5, for 30 sec. The lysate was centrifuged at 16,300 x g for 10 min, and the supernatant was coprecipitated with immunoglobulin fractions of normal BN serum, normal Lewis serum, BN antiserum to Moloney sarcoma cells (BNaMST), BN antiserum to tumor-associated antigens (BNaTAA), BN antiserum to murine leukemia virus (BNa-MuLV), BN antiserum to p30 (BNap30), BN antiserum to gp70 (BNagp70), Lewis antiserum to BN (LeaBN), and BN antiserum to BC5 tumor (BNaBC5). With BNaTAA and BNaMST, a cytoplasmic TAA with a mol wt of 85,000 was detected. In addition, BNaTAA detected three other species of cytoplasmic TAA with mol wts of 220,000, 170,000, and 39,000. The BNaTAA-precipitated entities were unique to MST cells and unrelated to viral, fetal, or histocompatibility antigens. (13 refs)

79-0488 Exogenous Immunoglobulin and the Macrophage Origin of Reed-Sternberg Cells in Hodgkin's Disease. (Eng) Kadin, M. E. (Dept. Lab. Medicine, SB-10, Univ. Washington, Seattle, WA, 98195); Stites, D. P.; Levy, R.; Warnke, R. *N Engl J Med* 299(22): 1208-1214; 1978.

To clarify the nature of Hodgkin cells and their immunoglobulin (Ig), the surface-membrane and cytoplasmic Ig of freshly isolated, viable Reed-Sternberg (R-S) cells from 14 Hodgkin's disease patients was examined with highly specific F(ab'), antisera, which consistently give monoclonal staining in non-Hodgkin lymphomas. Individual R-S cells were examined simultaneously for κ and λ light chains with the use of mixed F(ab'), fragments of antibodies labeled with fluorescein and rhodamine isothiocyanate. It was found that the Ig in R-S cells is predominantly IgG (in one case, IgM was also present) and is always polyclonal. It is probably derived from Ig bound to the membrane of R-S cells in vivo, possibly as the antibody portion of immune complexes circulating in the serum of Hodgkin's disease patients. The capacity of R-S cells to bind and internalize exogenous aggregates of IgG and immune complexes of sheep RBC with IgG or IgM and complement was confirmed in vitro; thus, R-S cells are similar to normal peripheral blood monocytes. The nonrandom uptake of Ig by R-S cells in vivo was inferred from the apparent absence of other common plasma proteins, albumin and fibrinogen, in freshly isolated R-S cells and exclusion by the cells of trypan blue dye. The uptake is probably mediated by the Fc receptor or antigen(s) associated with Hodgkin's disease at the cell membrane. The results favor a macrophage origin for the R-S cell. (29 refs)

79-0489 Effects on In Vitro Tumor Growth of Murine Macrophages Isolated from Sarcoma Lines Differing in Immunogenicity and Metastasizing Capacity. (Eng) Mantovani, A. (Istituto di Ricerche Farmacologiche "Mario Negri", Via Eritrea, 62--20157 Milan, Italy). *Int J Cancer* 22(6): 741-746; 1978.

The effects on in vitro tumor growth of murine macrophages isolated from a chemically-induced, strongly immunogenic, non-metastasizing FS6 sarcoma and from a weakly immunogenic, metastasizing line (mFS6) of the same tumor were investigated. Macrophages isolated from the FS6 sarcoma non-specifically inhibited growth and DNA synthesis of tumor cells in vitro. After culture, FS6 macrophages rapidly lost their cytotoxic activity and became capable of nonspecifically stimulating tumor growth in vitro. Macrophages obtained from the mFS6 tumor nonspecifically enhanced the proliferative activity of tumor target cells and this capacity was maintained when the macrophages were cultured. The results are in keeping with the hypothesis that mononuclear phagocytes may play a role in the regulation of tumor growth and metastasis. (28 refs)

79-0490 In Vitro Sensitization of Lymphocytes Against Murine Viral Associated Antigens by Antigen-fed Macrophages. (Eng) Treves, A. J. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Honsik, C.; Lieberman, M.; Decleve, A.; Feldman, M.; Kaplan, H. S. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 108-117; 1977.

Cell-mediated immunity against both viral particles and various viral antigens was induced in vitro by antigen-fed macrophages. Peritoneal radiation leukemia virus (RadLV)-fed macrophages obtained from (C57BL/Ka x BALB/c)F₁ mice sensitized spleen cells (SC) in vitro so that they became cytotoxic to the virus-infected target cells, BL-6(RadLV). Cell-free extracts from infected and noninfected (BL-5) fibroblast lines and noninfected intact BL-5 lines were also susceptible. Cell-free extracts from three nonproducer lymphoma cell lines (VL₁, RL-12, and R₀) were also immunogenic, but extracts from normal thymocytes and intact mouse embryo fibroblasts were much less so. Cellular components were not necessary for the sensitization, but direct incubation of viruses with SC did not result in immunogenic activity. SC sensitized with first-passage mouse embryo fibroblast-fed macrophages infected with BL/Ka(6) virus and then tested for cytotoxicity only showed activity against fibroblasts infected with the same virus. The effector capacity of macrophage-sensitized lymphocytes could be measured by an end-labeling assay of remaining target cells but not by a pre-labeling assay, as could directly sensitized lymphocytes. In vivo, RadLV-fed macrophages had no influence on tumor growth when injected simultaneously with VL₁ lymphoma cells, but they markedly inhibited tumor development and increased survival when injected 4 days before tumor cells. It is suggested that different subpopulations of T lymphocytes are induced by the sensitization procedures. (21 refs)

79-0491 A T-dependent Factor in Mouse Serum Suppressing Lymphocytic Anti-tumour Cytotoxicity

ty. (Eng) Rao, P. E. (Cornell Univ. Medical Coll., 1300 York Ave., New York, NY, 10021); Sussdorf, D. H. *Immunology* 35(6): 907-915; 1978.

The observation that sera of BALB/c mice bearing urethane-induced lung adenomas contained a factor capable of inhibiting the cytotoxicity of lymphocytes sensitized to the tumor is reported, and the results of experiments in which the factor was sought in the sera of non-tumor-bearing animals are presented. Sera from athymic mice, both normal and tumor bearing, were also examined, as well as sera from thymus-implanted nude mice. The cellular target of the factor was determined by absorption experiments using tumor cells, normal lymphocytes, or tumor-sensitized lymphocytes. The mol wt of the suppressive factor was estimated using Sephadex gel filtration and sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). The suppressive factor was stable to heating at 56 C for 30 min and was unaffected by freezing and thawing. Pretreatment of tumor targets with serum before the addition of lymphocytes was not protective, but pretreatment of sensitized lymphocytes with serum inhibited their cytotoxicity to the same extent as did treatment of the whole culture with serum. Suppressive activity could be removed from serum by absorption with sensitized, but not with unsensitized lymphocytes. While sera from syngeneic or adenoma-bearing nude mice were free of suppressive activity, the activity appeared in nude mice following thymus implantation. When whole BALB/c serum was fractionated on a Sephadex G-200 Column, suppressive activity equivalent to that found in the whole serum was observed consistently in protein fractions eluting in the region of 14,000 daltons. No activity was found in this region when sera lacking suppressive ability were separated. Electrophoresis of fractions representing the activity zone revealed a protein with a mol wt of 14,000 daltons that was present in fractions from active sera, but absent from fractions of inactive sera. Electrophoresis of fractions without suppressive activity did not produce this band. Both the activity zone in the Sephadex profile and the SDS-PAGE band could be demonstrated with sera from thymus-restored nude mice. The observations indicate the existence of a low-mol wt protein in the circulation of normal BALB/c mice that is capable of in vitro suppression of cell-mediated anti-tumor cytotoxicity. The presence of this factor appears to be thymus-dependent, and it seems to exert its effect by binding to sensitized killer lymphocytes. (24 refs)

79-0492 K Chain Variable Regions from Three Galactan Binding Myeloma Proteins. (Eng) Rao, D. N. (Lab. Cell Biology, NCI, NIH, Bethesda, MD, 20014); Rudikoff, S.; Potter, M. *Biochemistry* 17(25): 5555-5559; 1978.

Structural studies of the kappa light chains of the BALB/c mouse myeloma proteins X-24, X-44, and T-601, all of which display binding specificity for antigens containing $\beta(1 \rightarrow 6)$ -D-galactopyranosyl moieties, were carried out. Amino

acid (AA) sequencing and fragmentation by CNBr were used for the structural analysis. A high degree of homology was observed in the first 108 AA of the amino termini of the three proteins. X-24 and T-601 were identical over the first 99 AA and differed only at positions 100 and 106. X-44 differed from the others at position 96 in the third light chain complementarity determining region, but was identical to X-24 at position 106. The presence of a different AA in each protein at position 100 suggests the possibility of multiple genes existing for this segment of the molecule. The change of X-44 at position 96 of tryptophan for isoleucine is interesting, as it involves a change in all three codon bases. X-24 and T-601 are the first pair of light chains to exhibit perfect identity over their variable regions, and the minimal variation seen in all these anti-galactan light chains favors the hypothesis that at least one germ line is required to code for these structures. (37 refs)

79-0493 Self-Nonself Concept for Cancer and Diseases Previously Known as "Autoimmune" Diseases. (Eng) Levine, P. (Ortho Res. Foundation, Raritan, NJ, 08869). *Proc Natl Acad Sci USA* 75(11): 5697-5701; 1978.

The illegitimate glycosphingolipid antigens of the P blood group system and of the Forssman (Fs) tissue antigen in adenocarcinoma, which are foreign to the host, suggest the self-nonself concept, which applies also to diseases such as rheumatoid arthritis, lupus, glomerulonephritis, and idiopathic acute hemolytic anemia. In the presence of glycosphingolipid antigens such as ABO, P, and Fs, the normal serum of the homozygote recessive precursor contains antibodies for the missing antigen(s). The expected antibody to the Fs antigen was present in about 75% of normal men and women. In cancer sera, the incidence of anti-Fs was decreased to about 35%-40%. Anti-Fs was present in 90% of normal sera in the youngest group; this value gradually diminished in the other groups, and the incidence of the antibody in the 70-yr age group was about 60%. The rate of loss of anti-Fs with increasing years appears to parallel the gradual loss of anti-A and anti-B isoagglutinin titers. This phenomenon may be associated with the gradual diminution of protein synthesis with aging or the continuous accumulation of soluble immune complexes in the serum, or both. The self-nonself concept may also be the basis for the pathogenesis of rheumatoid arthritis, lupus erythematosus, idiopathic acute hemolytic anemia, and numerous other conditions classified as "autoimmune" diseases. Some of these diseases are induced by viruses or drugs or both. When a virus or drug attaches itself to the membrane of a tissue cell, the self is converted to nonself which, in rheumatoid arthritis, alters its self immunoglobulin (Ig) to nonself Ig. (31 refs)

79-0494 Activation of Latent Epstein-Barr Virus by Antibody to Human IgM. (Eng) Tovey, M. G. (Lab. Viral Oncology, Institut de Recherches Scientifiques

sur le Cancer, Villejuif, France); Lenoir, G.; Begon-Lours, J. *Nature* 276(5685): 270-272; 1978.

The activation of latent Epstein-Barr virus (EBV) by treatment of human lymphoid cell lines with antisera to human IgM is reported. Treatment of Burkitt's lymphoma-derived Raji cells with antiserum directed against human immunoglobulins increased the number of cells expressing the EBV-specific early antigen (EA) by up to 5,000-fold. Induction of EBV EA was greater with antiserum than with 5-iodo-2-deoxyuridine (IUdR) or 12-O-tetradecanoylphorbol-13-acetate and was greater with antiserum and IUdR combined than with either agent alone. The activity of the anti-human IgM serum was specific for human IgM, and its effect was due to its anti- μ -chain activity. EA induction by anti- μ antibody cannot be explained simply as a nonspecific mitogenic effect. The block in the abortive cycle of Raji cells appeared to be after EA and DNA polymerase synthesis and was independent of the level of induction. Variations in the responses of other cell lines to the anti-IgM antibody were observed, and they may have been due to differences in the amount and/or expression of surface-bound IgM. Activation of the latent EBV genome by antiserum to human IgM may result either from a direct stimulation of virus replication by the antiserum or from combination of the antiserum with surface-bound immunoglobulin. (33 refs)

desired specificity. Sp2/0-Ag14 was resistant to 8-azaguanine, died in HAT-supplemented medium, and had about 73 chromosomes. It was fused with spleen cells from mice immunized with trinitrophenyl (TNP)-derivatized keyhole limpet hemocyanin (TNP-KLH) to yield eight growing cultures. IgM, which did not have TNP specificity, was secreted by four of the cultures, and IgG, which did show TNP specificity, was secreted by the other four. The clones could be distinguished by the mobility of the light or heavy chain. Revertant hybridomas expressing the sheep RBC-specific IgG2b of the progenitor cell line constituted less than one in 5×10^4 of the TNP-specific hybridoma cells. As shown by their karyotypes, the TNP-specific cell lines were hybrids of Sp2/0-Ag14 and mouse cells. Ip injection of TNP-specific hybridoma cells into BALB/c mice caused tumors and yielded ascites fluid with high titers of the TNP-specific Ig. (12 refs)

79-0495 A Better Cell Line for Making Hybridomas Secreting Specific Antibodies. (Eng) Schulman, M. (Basel Inst. Immunology, Grenzacherstrasse 487, Postfach, 4005 Basel 5, Switzerland); Wilde, C. D.; Kohler, G. *Nature* 276(5685): 269-270; 1978.

A mouse myeloma cell line (Sp2/0-Ag14) was isolated that made no immunoglobulin (Ig) but could be fused with spleen cells to yield hybrids (hybridomas) secreting antibody of

PATHOGENESIS

- 79-0496 Malignant Lymphoma in Four of Five Siblings.** (Eng) Nagel, G. A. (Departement fur Innere Medizin, Kantonsspital Basle, Basle, Switzerland); Nagel-Studer, E.; Seiler, W.; Hofer, H. O. *Int J Cancer* 22(6): 675-678; 1978.

A family in which four of five sisters developed malignant lymphoma and two other relatives had Hodgkin's disease (HD) is reported. Two sisters had the nodular sclerosis type of HD, the third had the lymphocyte-depleted type, and the fourth had a diffuse small-cell reticulum sarcoma affecting the entire lymph-node system, spleen, tonsils, lungs, liver, kidneys, meninges, brain, peripheral nerves, and bone marrow. The first and last patients died of their diseases, while the disease in the other two sisters had remained in remission following radiotherapy. The histocompatibility antigen (HLA)-haplotypes were identical in the three patients studied, while that of the one healthy sibling differed. An uncle of the five sisters (one of their father's 16 siblings) and a second-degree cousin (son of the father's cousin) had both died with HD. It is possible that a genetically determined susceptibility to malignant lymphoma occurred in this family. (26 refs)

- 79-0497 Lymphoma after S.L.E. (Letter to Editor).** (Eng) Barrett, A. (Inst. Cancer Res., Sutton, Surrey SM2 5PT, England); Fitzharris, B. M.; Robson, T.; Smyth, J. F. *Lancet* 2(8099): 1102; 1978.

Two cases of non-Hodgkin lymphoma, one associated with systemic lupus erythematosus (SLE) and one with rheumatoid arthritis, are presented. The lymphomas developed many years after the onset of autoimmune disease, and immunodeficiency may have been a causative factor. Neither patient had received immunosuppressive drugs other than steroids. (no refs)

- 79-0498 Preleukemic Syndromes.** (Eng) Pierre, R. V. (Mayo Clinic, 200 First St. S.W., Rochester, MN). *Virchows Arch Cell Pathol* 29(1/2): 29-37; 1978.

To determine whether cytogenetic studies would be helpful in the diagnosis of preleukemic phases of acute nonlymphocytic leukemia (ANLL), and secondarily to study the prognostic significance of any observed cytogenetic abnormality, a prospective study was carried out on 284 patients with suspected preleukemia. Of these, 62 patients were identified with progression to overt ANLL. Of suspected preleukemic patients, 30% had cytogenetic abnormalities whereas

53% of patients progressing to ANLL exhibited cytogenetic abnormalities. From this data it is suggested that the presence of cytogenetic abnormalities aid in the recognition of preleukemia but are not specific for early leukemia. Furthermore, it is concluded that patients with defective chromosomes (as determined from banding studies) are more likely to develop overt ANLL. (16 refs)

- 79-0501 Erythrocyte Abnormalities Induced by Chemotherapy and Radiotherapy: Induction of Preleukaemic States?** (Eng) Renoux, M. (Service d'Hematologie Clinique, Hopital Beaujon, 100 boulevard du General Leclerc, 92118 Clichy Cedex, France); Bernard, J. F.; Torres, M.; Schlegel, N.; Amar, M.; Lopez, M.; Boivin, P. *Scand J Haematol* 21(4): 323-332; 1978.

Parameters frequently affected in leukemia, preleukemic states, and bone marrow insufficiency were studied in 21 patients with multiple myeloma (MM) and 33 patients with nonhematologic malignancies before and after chemotherapy. Fourteen of the cancer patients had received prior radiotherapy. Before chemotherapy, the only abnormality was found in the MM patients was an elevated HbF level in one patient. After chemotherapy, MM patients had the following RBC abnormalities: pyruvate kinase (PK) deficiency (58% of patients), increased HbF level (47%), abnormal bone marrow sideroblasts (30%), and modification of blood group antigens (BGA: 68%). No phosphofructokinase (PFK) deficiency was found. In the patients with nonhematologic malignancies, prechemotherapy abnormalities were found only in patients that had received prior radiotherapy, and they consisted of a slight decrease in PK activity (2 patients), decreased PFK activity (1), and modification of BGA (2). After chemotherapy, the patients with nonhematologic malignancies had the following abnormalities: PK deficiency (50%), PFK deficiency (20%), increased HbF level (10%), and modification of BGA (40%). In both patient groups, the

abnormalities, which are usually associated with dysmyelopoiesis and preleukemic states, generally appeared after three monthly courses of chemotherapy, and they appeared more frequently and with greater intensity after combined chemo- and radiotherapy. It is cautioned that none of these parameters are specific to malignant states. (41 refs)

- 79-0502 Abnormalities of Chromosome No. 1: Significance in Malignant Transformation.** (Eng) Rowley, J. D. (Dept. Medicine, Univ. Chicago, Chicago, IL, 60637). *Virchows Arch Cell Pathol* 29(1/2): 139-144; 1978.

To identify the nonrandom abnormalities of whole chromosomes as well as the specific region of chromosome involved, human hematologic malignancies were investigated. Results of banding studies disclosed that in myeloid cells from each of 35 patients with various disorders including acute leukemia, polycythemia vera, and myelofibrosis, clonal alterations leading to either an excess of chromosome number 1, or a partial excess of number 1, was accompanied by trisomy for bands 1q25 to 1q32. Analogous cytogenetic aberrations were consistently noted in solid tumors as well. Evidence showing that the break points in reciprocal translocations that involve chromosome Number 1 occurred almost exclusively in the short arm suggests that this arrangement was not the result of a particularly fragile site between these particular bands. It is now possible to correlate the nonrandom cytogenetic aberrations with specific gene loci. Further study may reveal the gene sequences related to malignancy. (23 refs)

- 79-0503 Cytogenetics of Acute and Chronic Myelofibrosis.** (Eng) Nowell, P. C. (Dept. Pathology, Sch. Medicine, Univ. Pennsylvania, Philadelphia, PA, 19104); Finan, J. B. *Virchows Arch Cell Pathol* 29(1/2): 45-50; 1978.

A review is presented of the relationship between studies of chromosome structure and the development of acute and chronic myelofibrosis. In both acute and chronic myelofibrosis, in addition to other lymphoproliferative disorders that initiate an increased risk for progression to leukemia, a clone of hemic cells with a chromosome defect is fairly common. Unfortunately, the presence or absence of a cytogenetic alteration has yet to show prognostic value with respect to subsequent clinical course. Chromosome studies indicate that no one particular karyotypic transformation can be associated with myelofibrosis specifically, as many of the same non-random alterations are found in other leukemic and preleukemic conditions. Additionally, both cytogenetic and isoenzyme data suggest that the fibrous tissue in the bone marrow is not related to the myeloproliferative clone. (9 refs)

- 79-0504 A Family with Acute Leukemia, Hypoplastic Anemia and Cerebellar Ataxia. Association with**

Bone Marrow C-Monosomy. (Eng) Li, F. P. (Sidney Farber Cancer Inst., 35 Binney St., Boston, MA, 02115); Potter, N. U.; Buchanan, G. R.; Vawter, G.; Whang-peng, J.; Rosen, R. B. *Am J Med* 65(6): 933-940; 1978.

A family case-study is presented in which the proband, a 6-yr-old boy, is the brother of three other boys who died with hematologic malignancies: the eldest brother died of acute myelogenous leukemia at 10 yr of age, and the second and third eldest brothers died of hypoplastic anemia at ages 5 and 9 yr, respectively. The surviving brother manifests abnormalities that suggest a preleukemic state such as mild pancytopenia, platelet dysfunction, and immunodeficiency. His 17-yr-old sister has a mild normochromic normocytic anemia. Cytogenetic banding studies revealed C-group monosomy in the bone marrows of the proband and third brother, and also that chromosome Number 8 was missing in the proband. At least four of the children and the father had cerebellar ataxia and evidence of a small cerebellum at autopsy or when examined by computerized axial tomography. It is concluded that the array of aberrations exhibited by this family may constitute a new genetic syndrome. (42 refs)

- 79-0509 Carotid Body Tumours. A Report of Twelve Cases.** (Eng) Bergdahl, L. (Thoracic Surgery Clinic, Karolinska Sjukhuset, Stockholm, Sweden). *Scand J Thorac Cardiovasc Surg* 12(3): 275-279; 1978.

Twelve case reports of carotid body tumors established by histological examination were collected from various hospitals throughout Sweden and are summarized. One patient was diagnosed to have such a malignant tumor 24 yr after receiving radiation treatment for a benign tumor on the same side of the neck. Although there is well documented evidence of thyroid carcinomas developing after such irradiation for benign neck disorders, the development of carotid body tumors has not been reported. Definitive diagnosis was obtained in 6 patients by carotid angiography, and in 1 patient (of 10 investigated) by fine needle biopsy. In 9 of the 12 patients, subadventitial removal of the tumor was performed and resulted in no recurrence during the mean follow-up period of > 8 yr. Although the other three patients died (cerebral infarction, myocardial infarction, and renal insufficiency), there was no evidence of recurrence. Although operation of carotid body tumors may require vascular reconstruction, it is concluded that subadventitial excision gives good prognosis. (28 refs)

- 79-0510 Bilateral Acinous Cell Tumors of the Parotid Gland.** (Eng) Nelson, D. W. (Dept. Otolaryngology, Henry Ford Hosp., Detroit, MI, 48202); Nichols, R. D.; Fine, G. *Laryngoscope* 88(12): 1935-1941; 1978.

The tenth reported case of bilateral acinous cell tumors of the parotid gland is presented. A 59-yr-old woman presented with a relatively pain-free swollen left parotid gland of 6 mo duration. Biopsy revealed an acinic cell carcinoma, and this diagnosis was confirmed upon left total parotidectomy. One year later, she complained of painful swelling in the right parotid gland. No discrete tumor was identified upon physical examination. After continued pain-free enlargement of the gland over the next year, a biopsy was performed. It revealed a diffuse acinic cell carcinoma that was removed by total right parotidectomy. Both tumor specimens were similar grossly and microscopically. The cut surface revealed many discrete, irregular, moderately firm tan nodules 0.2-1.0 cm in diameter replacing most of the parotid gland. These tumors, which arise from pluripotent duct cells or the secretory cells of the salivary gland acini, are weakly malignant. Microscopically, they bear a striking resemblance to the normal acinous tissue of the parotid. The cells are in close contact with small amounts of vascular stroma, and they are often arranged as well-formed acini with an abundant basophilic granular cytoplasm. The cells may be round or polygonal with small, dark, eccentric nuclei. Nucleoli are usually indistinct and mitotic figures uncommon. The clear cell component is stained poorly or not at all with hematoxylin-eosin but may be stained with PAS. The tumors do not exhibit histologic criteria by which local aggressive or metastatic behavior can be predicted. (19 refs)

- 79-0511 The Pathogenesis of Cancer (Meeting Abstract).** (Eng) Louis, C. J. (Dept. Pathology, Univ. Melbourne, Austin Hosp., Heidelberg, Victoria, Australia). *Pathology* 10(4): 392; 1978. (no refs)

- 79-0512 Giant-Cell Tumor of the Maxilla. Report of a Case.** (Eng) Ajagbe, H. A. (Dept. Dentistry, Univ. Coll. Hosp., Ibadan, Nigeria); Samuel, I.; Daramola, J. O. *Oral Surg* 46(6): 759-764; 1978.

A case is reported of a giant cell tumor arising in the right mandible of a 5-yr-old boy. The patient was seen for a mass of 4 months' duration that extended to the infraorbital regions superiorly, the soft palate posteriorly, and expansively anteriorly. An incisional biopsy identified the mass as a giant-cell, grade II tumor. The tumor was subsequently removed in a large piece through a Weber-Fergusson incision, and after 23 mo the recovery remains uneventful. Pathologically, the 6 x 5 x 5-cm fleshy tumor was composed of maxillary tissue (60 g), spongy in appearance, light brown in color, and gritty to the touch. There was also a nodular mass (18 g) present, consisting of granular, gritty brown tissue containing occasional bone spicules. Histologically, the tumor was composed of a spindle-shaped stroma in which multinucleated giant cells were found. The 5 to 50 nuclei per giant cell showed a mild degree of pleomorphism and scattered mitotic figures, and the giant cells in general stood out distinctly from the surrounding stroma. No areas of hemorrhage or hemosiderin-laden macrophages were present in the stroma. In differential diagnosis, hyperparathyroid function, osteogenic sarcoma, and epulides must be ruled out. (11 refs)

- 79-0513 Fibrous Histiocytoma of the Head and Neck: A Case Report.** (Eng) Hutchinson, J. C. (1753 W. Congress Parkway, Chicago, IL, 60612); Friedberg, S. A. *Laryngoscope* 88(12): 1950-1955; 1978.

A case report of a recurring malignant fibrous histiocytoma (FH) of the submandibular gland is reported, and 35 literature cases of FH originating in various deep structures of the head and neck (excluding the orbit) are reviewed. A 62-yr-old woman underwent enucleation of a left submandibular gland tumor that was considered a benign FH, although malignancy could not be ruled out. A recurrence at the same site 29 mo later was also enucleated, but this lesion was considered a malignant FH. Approx 1 yr later, a segmented mandibulectomy was performed to remove a 3-cm malignant FH that had arisen over the midportion of the body of the left mandible. Six months later, a similar 3-cm mass was removed from the midportion of the left cheek, and 6 mo after this surgery, three isolated metastatic nodules were resected from the right lung. The patient remains clinically free of disease 15 mo after the last recurrence. FH are composed of fibrocytes and histiocytes in varying ratios, and they may also possess tumor

giant cells. Synonyms for this tumor are numerous, and xanthofibroma, fibroanthoma, and dermatofibroma are included among the 14 listed. One percent prove to be malignant, and 25% of these metastasize. Diagnosis of malignancy must be made by clinical (metastases) rather than histologic means. Electron microscopy has not proved useful in determining malignancy. In the head and neck region, the FH appears to be more common in men by a ratio of 3:1. Most patients are in the fifth decade, but the age range is wide. (14 refs)

- 79-0514 Sinus Histiocytosis with Massive Lymphadenopathy (Rosai-Dorfman Disease): Report of a Case with Respiratory Tract Involvement.** (Eng) Carpenter, R. J. (Dept. Otorhinolaryngology, Mayo Clinic and Mayo Foundation, 200 First St., S. W., Rochester, MN, 55901); Banks, P. M.; McDonald, T. J.; Sanderson, D. R. *Laryngoscope* 88(12): 1963-1969; 1978.

A case of sinus histiocytosis with massive lymphadenopathy (SHML) (Rosai-Dorfman disease) in a patient with extensive nasal and tracheobronchial involvement and massive cervical lymphadenopathy is presented. A 44-yr-old Caucasian woman was admitted with complaints of nasal obstruction, stridor, and recurrent cervical adenopathy. Indirect laryngoscopy upon admission showed circumferential subglottic narrowing due to a band of erythematous granular tissue. Lymph node, tracheal, and nasal biopsies indicated submucosal infiltration by lymphoid cells and histiocytes engulfing cellular debris. Capsular fibrosis, sinusoid enlargement, and dense plasmacytosis were also present in the lymph nodes, and the diagnosis was amended to SHML. Four months later, the subglottic narrowing and cervical node enlargement had progressed, and bilateral parotid swelling was first noted. Erythematous, granular-appearing polypoid tissue that extended from the immediate subglottic area downward for 3-4 cm and narrowed the lumen to about 50% normal diameter was identified upon direct laryngoscopy and bronchoscopy. Similar polypoid masses were found on the right wall of the midtrachea, on the anterior wall of the distal trachea, and in the right main bronchus (occluded 40%). Stridor and dyspnea were immediately relieved upon removal of this tissue. However, obstruction recurred 3 mo later. It was successfully treated by chlorambucil (6 mg/day) and prednisone (100 mg every other day), even though the disease was proved histologically to be nonneoplastic. The symptoms disappeared rapidly on this regimen and the patient currently (5 mo later) feels well. Concomitant upper and lower airway involvement in addition to cervical adenopathy is an unusual finding in SHML. (11 refs)

- 79-0515 Characteristics and Diagnostic Approaches in the Detection of Nonapparent Bronchogenic Carcinoma.** (Eng) Hofner, W. (Dept. Radiology, Second Medical Univ. Clinic, Garnisongasse 13, A-1090 Vienna,

Austria); Kuester, W.; Seidl, G. *Radiol Clin (Basel)* 47(6): 412-422; 1978.

Three case reports demonstrate that a negative chest x-ray does not exclude a bronchogenic carcinoma. However, tomography allows early detection of small tumors in the hilum or tumors hidden in the mediastinal shadow in the absence of parenchymal changes. (20 refs)

- 79-0516 Congenital Solitary Cysts of the Liver and Spleen.** (Eng) Williamson, R. C. (Univ. Dept. Surgery, Bristol Royal Infirmary, Bristol, England); Ramus, N. I.; Shorey, B. A. *Br J Surg* 65(12): 871-876; 1978.

Three symptomatic cases of congenital solitary cyst are reported, one in the liver (49-yr-old woman) and two in the spleen (18- and 30-yr-old women). The incidence, pathology, presentation, diagnosis, and complications of these cysts are summarized. One complication of the hepatic cysts is malignant change. (43 refs)

- 79-0517 Electron Microscopic Findings in a Malignant Hepatoma after Oral Contraception.** (Ger) Hatzibujas, J. (Institut für Pathologie I, Bundesknappschaft Am Deimelsberg 34A, D-4300 Essen 14, W. Germany); Ueberberg, H.; Stoldt, R.; Breining, H. *Z Gastroenterol* 16(10): 616-624; 1978.

The results of an electron microscope (EM) study of a hepatocellular carcinoma found in a 24-yr-old woman are described. Preoperatively, the clinical, laboratory, and histological findings suggested chronic aggressive hepatitis. The patient had been taking an ovulation-inhibiting contraceptive for 5 yr, until only a few wk before surgery. After biopsy, diagnosis, and surgical removal of the tumor, the patient died from bleeding from a hepatic vein. EM study showed numerous mitochondria and few other organelles in the tumor cells. Glycogen was mostly extracellular. Lysosome membranes showed myelin-like residual bodies. Deep invagination was the most marked nuclear change. Endoplasmic reticulum (ER), mitochondria, and glycogen were found within the invaginated spaces. Finger-like nuclei containing ER, ribosomes, glycogen, and lipid drops were also found. The mitochondria were swollen, with rudimentary cristae and a homogenous matrix. They had polymorphic forms and were often interdigitated. Although many of these characteristics, such as invagination of the nuclei, have been found previously in tumors, the EM findings cannot be considered specific for malignant tumors of the liver. In contrast to several other reports, no giant mitochondria with paracrystalline inclusions were found. (18 refs)

- 79-0518 Early Endoscopic Features of Stomach Cancer and Its Mode of Growth.** (Eng) Hisamichi, S.

(Cancer Detection Center, Miyagi Cancer Society, Kamisugi 6-Chome, 2-81, Sendai 980, Japan); Shirane, A.; Sugawara, N.; Asaki, S.; Yanbe, T.; Ito, S.; Funada, K.; Hatori, S.; Ikeda, T.; Ito, Y.; Masuda, Y.; Ooshiba, S. *Tohoku J Exp Med* 126(3): 239-246; 1978.

Morphologic changes and early endoscopic features of 14 cases of advanced and 27 cases of early stomach cancer were studied. Thirty-five patients were men, 6 were women. Fifteen cases had infiltrated the gastric mucosa (mean age 57.3), 12 had infiltrated the submucosa (58.5), 9 had infiltrated the muscularis propria or had extended to the submucosa (59.0), and 5 had infiltrated the serosa or more deeply (49.8). The earliest endoscopic signs consisted of redness (12 cases), small polypoid lesions (7 cases), and flat mucosa with slight unevenness and small depressed lesions (a few cases). Redness or a small depressed lesion tended to develop into the superficial and depressed or excavated types of cancer, but small polypoid lesions tended to develop into the superficial, elevated type. The features of early stomach cancer could not be used to determine the type of advanced cancer that would develop. The av time from first endoscopic finding to the diagnosis of early cancer was 44 mo, and the av time from early cancer to advanced disease was 33.4 mo. There was no difference in rate of progression between differentiated vs undifferentiated cancers or protruding vs depressed types. Using a least squares method, the size of the cancer lesion was correlated with observation period for advanced disease but not early disease. (31 refs)

79-0519 Morbid Changes of the Mandible in Familial Polyposis of the Colon. (Eng) Shoji, K. (Third Dept. Internal Medicine, Tohoku Univ. Sch. Medicine, Sendai 980, Japan); Watanabe, H.; Goto, Y.; Yamada, N. *Tohoku J Exp Med* 126(3): 289-293; 1978.

Morbid changes of the mandible were investigated in 11 patients (9 men, 2 women aged 15-48 yr) with familial polyposis coli (FPC) admitted to a Japanese hospital over the past 15 yr. Ten patients and six unaffected family members underwent orthopantomography of the mandible: the 11th patient had died at age 23 of cancer of the sigmoid colon, and radiographic and histological studies were made of the excised mandible. Sclerotic masses of the mandible were found in 10/11 patients; in some patients, they were also found in the maxilla. The number of sclerotic masses ranged from 2 to 11, and they were associated with odontomas in 2 patients and impacted teeth in 1. A radiographic study of the excised mandible of the 11th patient revealed 11 sclerotic masses, each approx 5 mm in diameter, and 1 impacted tooth. Upon buccolingual cross section of the mandible in the canine area, central osteomas composed of mature lamellar tissue of bone were identified. Sclerotic masses were also found in 2/6 unaffected family members and in 7/60 other dental patients and 0/10 colonic adenoma patients chosen as controls. These results support the view that Gardner's syndrome and FPC are

etiologically identical lesions with minor differences due to variable gene expression. (6 refs)

79-0520 Malignant Potential of Chronic Ulcerative Colitis. Preliminary Report. (Eng) Nugent, F. W. (Dept. Gastroenterology, Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA, 02215); Haggitt, R. C.; Colcher, H.; Kutteruf, G. C. *Gastroenterology* 76(1): 1-5; 1978.

In an attempt to further define the histologic and clinical risk factors of the premalignant state of ulcerative colitis (UC), a two-part study was undertaken comprising a retrospective analysis of patients with UC and carcinoma and a prospective analysis of patients with long-standing UC. Of 23 patients with colon carcinoma and chronic UC, 22 exhibited dysplasia of colonic epithelium remote from the cancer. The prospective evaluation reviewed clinical data as well as rectal and colonoscopic biopsy specimens on 36 patients with chronic UC, 12 with Crohn's colitis, and 12 with miscellaneous disorders. Of the patients with chronic UC, 8 had dysplasia, 6 have had colectomy, and 2 of the latter had carcinoma. No patient without chronic UC had dysplasia. It is concluded that patients with chronic UC should have periodic rectal and colonoscopic biopsies, and those demonstrating moderate to severe dysplasia require colectomy because of the increased risk of colon carcinoma. (15 refs)

79-0521 Cancer of the Rectum Following Colectomy and Ileorectal Anastomosis for Ulcerative Colitis. (Eng) Baker, W. N. (Surgical Unit, London Hosp., London E1 1BB, England); Glass, R. E.; Ritchie, J. K.; Aylett, S. O. *Br J Surg* 65(12): 862-868; 1978.

The case records of 384 patients treated for ulcerative colitis by colectomy and ileorectal anastomosis by one surgeon between 1952 and 1976 were reviewed. Of the 374 who have been followed-up (for periods up to 23 yr), 22 are known to have developed rectal carcinoma. Within 10 yr of the operation, no rectal carcinoma was found in 3,534 patient-yr. The risk was 1 in 185 patient-yr between the 10th and 20th yr and 1 in 115 patient-yr between the 20th and 30th yr. The overall risk was $6 \pm 2\%$ at 20 yr and $15 \pm 4\%$ at 30 yr. Stress is placed on the need to meticulously follow up all cases. It is suggested that dysplasia in rectal mucosal biopsies may identify the patient at high risk and facilitate rectal excision before the onset of rectal carcinoma. (45 refs)

79-0522 Oestrogen Receptor Content of Primary Breast Tumours as a Prognostic Indicator of Early Recurrence (Meeting Abstract). (Eng) Maynard, P. V. (Tenovus Inst. Cancer Res., Welsh Natl. Sch. Medicine, Cardiff, CF4 4XX, Wales); Davies, C. J.; Elston, C. W.; Blamey,

R. W.; Griffiths, K. *J Endocrinol* 79(2): 50P-51P; 1978. (3 refs)

79-0523 Metastatic Bone Involvement in Gynecological Malignancies. (Eng) Brufman, G. (Dept. Oncology, Sharett Inst., Hadassah Univ. Hosp., POB 499, Jerusalem, Israel); Krasnokuki, D.; Biran, S. *Radiol Clin (Basel)* 47(6): 456-463; 1978.

The case reports of four women in whom metastatic bone involvement in a gynecological malignancy was diagnosed ante mortem are presented, and similar cases from the literature are reviewed. An osteolytic lesion in the lesser trochanter of the right femur was identified in a 69-yr-old woman while she was undergoing surgery for endometrial carcinoma. She was successfully treated with radiation and hormone therapy. Case 2 was a 57-yr-old woman who responded well to cobalt-60 radiation and intrauterine radium application for a Stage IIb squamous cell carcinoma of the cervix. Three years later, an osteolytic lesion in the left sacroiliac joint was successfully treated with radiation therapy. Case 3, a 43-yr-old woman, underwent total abdominal hysterectomy and bilateral salpingo-oophorectomy for a mesonephric carcinoma of the ovary. Three years later, an osteolytic lesion in the right femur plus a periosteal reaction appeared that were managed with radiation + chemotherapy. The fourth case, a 46-yr-old woman, underwent simple vulvectomy for squamous cell carcinoma of the vulva, and 8 mo later an osteolytic lesion was noted in the lower left tibia. Radiation therapy produced a good response, but 5 mo later the patient was rehospitalized for a pathological fracture of the left tibia with accompanying multiple metastatic lesions of the skin of the abdomen and both legs. Gynecological tumors ordinarily spread through the lymphatic system, and only in the most advanced cases is hematogenous spread noted, usually at necropsy. Therefore, these findings of hematogenous spread to bone in living patients are unusual. (13 refs)

79-0524 Cytologic Changes of Cervical Cancer According to the Degree of Invasion. (Eng) Yajima, A. (Dept. Obstetrics and Gynecology, Tohoku Univ. Sch. Medicine, Sendai 980, Japan); Teshima, K.; Noda, K. *Tohoku J Exp Med* 126(13): 295-299; 1978.

Cervical scrapings from 86 patients with carcinoma in situ (A), 91 with early invasive cancer (stromal invasion ≤ 5 mm B), and 50 with advanced cancer (C) were examined microscopically and analyzed numerically, and the results were used to try to determine the morphologic extent of the lesions. The number of malignant cells in the preparation increased with the extent of the lesion (from 31.4% to 65.9% to 92%). The occurrence of irregularly distributed, coarsely granular chromatin increased with the progression A to B to C. Anisocytosis, inclusion cells, and cellular detritus all likewise increased with increasing invasiveness, and in general these

patterns continued on a more specific scale when early invasive cancer was subdivided into four categories based on depth of invasion (1, 2, 3, or 5 mm). The ratio of malignant cells in the deep layer to malignant cells in the entire layer was 81% in A, 61% in B, and 55% in C. There was also an increase in the ratio of malignant cells to dysplastic cells with progression of the cancer. Hyperchromatism was not a good indicator of malignancy, as 89.5% of A and 100% of B and C cells had hyperchromatic nuclei. (18 refs)

79-0525 Ultrastructure of Adenocarcinoma of the Uterine Cervix (Meeting Abstract). (Eng) Okudaira, Y. (Dept. Gynecology, Center Adult Diseases, Osaka, Japan); Hayakawa, K.; Matsui, Y. *J Electron Microsc (Tokyo)* 27(4): 384; 1978. (no refs)

79-0527 Ultrastructural Studies of Experimental Yolk Sac Tumors in the Rat (Meeting Abstract). (Eng) Teshima, S. (Dept. Pathology, Hokkaido Univ. Sch. Medicine, Sapporo, Japan); Nakamura, K.; Aizawa, M.; Sakashita, S. *J Electron Microsc (Tokyo)* 27(4): 384; 1978. (no refs)

79-0528 The Prognostic Significance of Cytologic Differentiation Grades in Estrogen-treated Prostate Carcinoma. Course Control of 496 Carcinoma Patients Treated with Estrogen for 5 Years. (Ger) Faul, P. (Urologische Abteilung, Stadt Krankenhaus, Bismarckstrasse 23, D-8940 Memmingen, W. Germany); Schmiedt, E.; Kern, R. *Urologe [A]* 17(6): 377-381; 1978.

The cytologic differentiation grades of 496 estrogen-treated prostatic carcinoma patients (av age 68-69 yr) correlated with their prognosis. Av survival time was 6.9 yr for those with highly differentiated tumors, 2.6 yr for those with poorly differentiated tumors, and 1.9 yr for those with anaplastic carcinomas. The short survivals of those with the latter two

types of carcinoma suggest that the use of estrogens in these patients should be questioned. (28 refs)

79-0529 Cytologic Grading of Prostatic Carcinoma. (Ger) Voeth, C. (Pathologisches Institut, Städtisches Krankenhaus Neu-Perlach, Oskar-Maria-Graf-Ring 51, D-8000 Munich 83, W. Germany); Droese, M.; Steuer, G. *Urologe A* 17(6): 367-370; 1978.

The cytological differentiation grade (Esposti's method) was compared with the histological differentiation grade (Dhoms' method) for 92 prostate carcinomas. Agreement was found in 43 cases. The cytologic grading was reproducible in 60.9% of the cases; in 39.1%, the difference between the first and second evaluation was one grade. The omission of cellular atypia from the cytologic criteria, leaving only microglandular structure and cell dissociation, is suggested to make cytologic grading less subjective and more reproducible. EPIDEMIOLOGY AND BIOMETRY

- 79-0531 Mediastinal Tumours. A Follow-up Study of 208 Patients.** (Eng) Luosto, R. (Dept. Thoracic and Cardiovascular Surgery, Univ. Central Hosp., Helsinki, Finland); Koikkalainen, K.; Jyrälä, A.; Franssila, K. *Scand J Thorac Cardiovasc Surg* 12(3): 253-259; 1978.

During the period 1954-1973, 208 patients were referred to a Finnish hospital for treatment of mediastinal tumors. Forty-nine patients had malignant tumors (24%), 86 benign tumors and 73 nonneoplastic lesions. The most common histologic types were neurogenic tumors and malignant lymphomas, followed by thymomas and teratomas. Most nonneoplastic lesions were cysts. Thirty-five percent of the malignant tumors were asymptomatic, compared with 65% of the benign tumors and 66% of the nonneoplastic lesions. The most common symptom was pain, which occurred in one-fifth of the patients. The most useful diagnostic method was chest x-ray examination. However, a final diagnosis could usually be made only at operation. Thirteen malignant tumors were excised radically, 18 palliatively, and 18 were only biopsied. Almost all benign tumors were radically excised. Forty-four patients received postoperative radiation therapy and 6 received chemotherapy. The hospital mortality was 8.2% for patients with malignant tumors and 1.9% for those with benign tumors. At the end of the follow-up period, which ranged from 2 to 21 yr (median 10.3 yr), 41% of the patients with malignant tumors were alive. Two patients with benign tumors had died of an apparently malignant change in a neurofibroma. (15 refs)

- 79-0532 Estrogen Replacement Therapy and Endometrial Carcinoma.** (Eng) Rauramo, L. (Dept. Obstetrics and Gynaecology, Turku Univ. Central Hosp., Hämeenkatu 4, SF-20520 Turku 52, Finland). In: *Front Horm Res* 5: 117-125; 1978.

History of estrogen use was investigated by interview in 317 Finnish patients treated for endometrial cancer between 1970 and 1976 and in 304 healthy controls matched for age, wt, and social class. Only 9% of the cancer patients had ever taken estrogens, and the mean duration of use was 8 mo (range, 1-46 mo), but 19% of the control women reported taking estrogens for an av of 15 mo (1-84 mo). One incidental finding that was interesting concerned the use of other medication. When asked if they had been regularly taking other medication at the time of cancer diagnosis, 68% of cancer patients replied affirmatively. Most were being treated for hypertension (26%) and for congestive heart failure (22%); 6% were receiving analgesics. Only 37% of controls were

receiving other medication at a comparable point in time, with 14% being treated for hypertension. This study did not demonstrate an association between estrogen use and endometrial carcinoma, contrary to recent studies in the US (and other countries). This discrepancy may be due to qualitative and quantitative differences in the estrogen replacement therapies. (6 refs)

- 79-0533 Cancer Risk in Women with Uterine Myoma.** (Ger) Grosse, H. (Pathologisch-Anatomische Abteilung der Frauenklinik, Bezirkskrankenhaus Stralsund, Billrothstr. 22, DDR-23 Stralsund, E. Germany); Hohlbein, R.; Suffert, D.; Feiste, V. *Zentralbl Gynaekol* 100(10): 642-649; 1978.

The cancer risk of women with myoma was studied in an autopsy series and compared with controls (autopsy series without myoma or with past hysterectomy). In the autopsy series of women without myoma, gastric cancer was by far the most frequent tumor, followed by carcinomas of the intestines, bile ducts, and uterine cervix. Among the autopsied patients with past hysterectomy, breast cancer and carcinomas of the bile ducts, intestines, and stomach are most frequent. Breast carcinoma was most frequent in the autopsy series with myoma, followed by carcinomas of the stomach, bile ducts, intestines, and endometrium. Compared with the controls, the myoma patients showed a slightly increased incidence of adipositas, hypertension, lung embolism and myocardial infarction. Cancer was found in 336/1,306 autopsied women with myoma (25.7%), in 170/577 hysterectomized patients (29.5%), and in 2,472/8,243 controls (30%), ie, the findings do not indicate any increase in the cancer risk of patients with uterine myoma. Malignant transformation of the uterine myoma was seen in 0.7% of all cases. (52 refs)

- 79-0534 Endometrial Pathology and Its Relation to Estrogen Therapy in Patients with Hypogonadism.** (Eng) Rosenwaks, Z. (Dept. Pediatrics, Johns Hopkins Univ. and Hosp., Baltimore, MD, 21205); Urban, M. D.; Wentz, A. C.; Lee, P. A.; Parmley, T. H.; Migeon, C. J.; Jones, G. S.; Woodruff, J. D. *Pediatrics* 62(6, part 2, Suppl): 1184-1188; 1978.

The relationship between estrogen (EG) therapy and endometrial histology was investigated in 43 hypogonadal patients (av age 24.3 yr) receiving daily cyclic exogenous EG therapy for an av of 7.2 yr due to some variant of gonadal dysgenesis (41) or hypopituitarism (2). The therapy consisted of conjugated EG's (36 patients), conjugated EG's + diethyl-

stilbestrol (DES: 5), or DES only (2). Forty patients were receiving sequential EG/progesterone therapy, 3 EG therapy only. There were seven abnormal biopsies: six cases of benign cystic hyperplasia (BCH) and one of atypical hyperplasia. In the three BCH patients for whom data were available, the condition improved with reduced EG dose. The condition of the atypical hyperplasia patient, who initially refused surgical treatment, worsened; an epidermoid adenocarcinoma was identified upon subsequent hysterectomy. She had received the largest lifetime EG dose (20,320 mg) and had one of the longest treatment durations (19 yr). The patients were shown to be at statistically greater risk for abnormal endometrial biopsy findings if they had received a lifetime dose of conjugated EG's $\geq 2,500$ mg, the durations of EG therapy was > 7 yr, and the dose of conjugated EG's at biopsy was > 1.25 mg/day. The total lifetime progesterone dose was not correlated with endometrial pathology, nor was the occurrence of abnormal bleeding. (21 refs)

- 79-0535 Cancer of Ovary in Israel (1966-1971).** (Eng) Schenker, J. G. (Dept. Obstetrics and Gynecology, Hadassah Univ. Hosp., Jerusalem, Israel); Mazzor, M. *Gynecol Oncol* 6(5): 397-410; 1978.

The epidemiology and clinical course of carcinoma of the ovary in Israel during 1966-1971 were studied. The incidence of primary carcinoma of the ovaries was 16.2/100,000 in women aged > 15 yr. Seventy-five percent of the patients were aged 45-74 yr. Women of European/American origin had three- to fourfold higher incidence of ovarian cancer than those of Asian/African background. Fifty-one percent of the patients were diagnosed at an advanced stage of the disease, with only 14.5% being diagnosed at Stage 1A. The most frequent tumor was serous cystadenocarcinoma (41%); there was no significant predilection for involvement of one ovary or the other. The most frequent presenting symptoms were lower abdominal pain, abdominal enlargement, vaginal bleeding, and acute abdominal symptoms. The 5-yr survival rate was 22.2%, the 3-yr survival rate 28%. Factors affecting prognosis were age of the patient, presenting symptoms, clinical stage of the disease at diagnosis, histology of the tumor, and type of treatment. (24 refs)

- 79-0537 Possible Protection from Breast Cancer by Oral Contraceptives (Meeting Abstract).** (Eng) Gambrell, R. D. (Dept. Obstetrics and Gynecology, Wilford Hall United States Air Force Medical Center, Lackland Air Force

Base, TX); Massey, F. M.; Castaneda, T. A.; Boddie, A. W. *Fertil Steril* 30(6, Suppl): 754-755; 1978. (no refs)

- 79-0538 Oral Contraceptives and Breast Disease in Premenopausal Northern Albertan Women.** (Eng) Lees, A. W. (Cross Cancer Inst., Univ. Alberta, Alberta, Canada); Burns, P. E.; Grace, M. *Int J Cancer* 22(6): 700-707; 1978.

A prospective study on oral contraceptive use and breast disease in northern Alberta is presented. All women aged 30-49 yr who were examined at one diagnostic breast clinic were included in the study; 301 women with malignant breast cancer, 696 with benign breast disease confirmed by biopsy, and 548 women who did not receive a biopsy because there was no apparent breast disease were evaluated in terms of relative risk of breast cancer due to history of oral contraceptive use. All women selected were classified as recent users (REU) if contraceptives had been used in the past year. Otherwise, they were classified as former users (FRU). Length of use was divided into categories of ≤ 12 mo (S), 13-59 mo (M), or ≥ 60 mo (L). Considering duration of use only, the relative risk (RR) of developing breast cancer was significantly decreased in S users (0.6), increased to 1.4 among M users, and unchanged (1.0) in L users compared to never-users. When recent or former use is considered, the RR was ≥ 1 for all REU, while among FRU, the RR was reduced to 0.3 for S users and to 0.5 for L users but was 1.3 for M users. When the presence of a previous biopsy was considered, REU had a significantly increased RR of 5.0, while users of L duration had an increased RR of 9.2 (also significant) and M users had an increased RR of 2.3. In the M group without biopsy the RR was increased to 1.3, whereas in the S and L groups it was < 1.0 , tending to support theories that preexisting subclinical breast cancer is induced by oral contraceptives after several months of use and is only identified in ensuing years. (38 refs)

- 79-0539 Urinary Bladder Carcinoma in Biopsy Material During the Last 50 Years: Changes in Sex and Age Distribution and Frequency.** (Ger) Schubert, G. E. (Pathologisches Institut der Kliniken, Stadt Wuppertal, Arrenberg Strasse 20-56, D-5600 Wuppertal 1, W. Germany); Steinert, M. *Urologe A* 17(6): 361-366; 1978.

The frequency, sex, and age distribution of the urinary bladder biopsies performed at a clinic in Wuppertal, W. Germany, from 1927 to 1957 (T1) and from 1972 to 1976 (T2) were compared. T1, 234 bladder carcinomas (BC) were found among 440 biopsies; during T2, 655 BC were found among 1,634 bladder biopsies. The male:female ratio was 3.4 in T1 and 2.6 in T2. The age distribution curve for T1 showed a peak at 56-60 yr and a secondary peak at 66-70 yr. The youngest patients were 26-30 old. In contrast, the curve for T2 had a sharp peak at 66-70 yr, and the youngest patients

were 31-35 yr old. The proportion of transitional cell BC was 81.2% in T1 and 80.0% in T2; that of squamous cell BC was 2.8% in T2 and 5.1% in T1. Papillomas were found in 14% of all bladder biopsies in T1 vs 32% in T2. The fraction of well-differentiated BC increased in T2 compared to T1. The incidence of BC found in bladder biopsies climbed from 31.2% in 1972 to 52.5% in 1976. It seems doubtful that indications for biopsy have changed enough to account for this increase. No clear relationship between occupation and BC was found. (22 refs)

- 79-0540 Volatile Nitrosamines in Some Traditional Southern Chinese Food Products.** (Eng) Huang, D. P. (Medical and Health Dept., Inst. Radiology and Oncology, Queen Elizabeth Hosp., Kowloon, Hong Kong, China); Ho, J. H.; Gough, T. A.; Webb, K. S. *J Food Safety* 1(1): 1-6; 1977.

Due to the previous association seen between nasopharyngeal carcinoma and consumption of Cantonese salted fish in Southern Chinese populations attributed to the presence of nitrosamines, other salted food products common to the Southern Chinese diet were also tested for these compounds by gas chromatography and high resolution mass spectrometry. Pork sausage, goose-liver sausage, salt-dried beans, soya bean paste, soy, shrimp paste, oyster sauce, soyabean curd, salt-dried egg yolk, fish sauce, anchovies, croaker, red snapper, white herring, yellow croaker, and mixed fish heads were purified, extracted, concentrated and tested for the presence of seven different nitrosamines. Only N-nitrosodimethylamine was present in two samples of anchovies, one sample of croaker, three samples of white herring, and two samples of yellow croaker. The levels of this nitrosamine in these foods were no higher than those encountered in European cultured meats. No other volatile nitrosamines were detected in any other salted foods tested, a total of 34 different samples. This study does not rule out the possibility that nitrosamines are formed from these foods either during cooking or after ingestion. (19 refs)

- 79-0541 Nitrate Nitrogen Levels in Drinking Water of Urban Areas with High- and Low-risk Populations for Stomach Cancer: An Environmental Epidemiology Study.** (Eng) Zaldivar, R. (International Res. Group Cancer Epidemiology Human Ecology, 5055 N.W. 7th St, Suite 606, Miami, FL, 33126); Wetterstrand, W. H. *Z Krebsforsch* 92(3): 227-234; 1978.

A correlation study between mean nitrate levels (ppm) in drinking water samples (total 1,389) of Chilean urban areas and age-adjusted death rates per 100,000 population from stomach cancer, by province or region and sex, was made. Drinking water samples from all provinces had a weighed mean of 1,446 ppm, with a range of 0.00-30.00 ppm. Nitrate levels showed a positive but not significant association with

male death rates. The correlation coefficient was +0.0335. Similarly, the levels exhibited a positive but not significant correlation with female death rates ($r = +0.0486$). When nitrate levels and male ($r = 0.1367$) or female ($r = +0.1143$) death rates were studied by region, positive but insignificant correlations were detected. Using Cochran's approximation, mean nitrate levels in drinking water samples from six provinces with 50% of the Chilean population decreased from 1,835 in 1953-1955 to 1,291 ppm in 1973-1975, but there was no significant difference ($t = 1.32$) between the two values, except in samples from Santiago Province ($t = 2.11$, $p < 0.05$). Provinces (south central area) with the highest gastric cancer mortality rates in the world for women (up to 40.8/100,000), and ranking second for men (up to 84.1/100,000), exhibited a low mean level (0.825 ppm). (25 refs)

- 79-0542 The Agricultural Use of Nitrate Fertilizers (Tons of N) in Provinces of Chile with High- and Low-risk Populations for Gastric Carcinoma.** (Eng) Zaldivar, R. (International Res. Group Cancer Epidemiology & Environmental Hygiene, 5055 N.W. 7th St., Suite 606, Miami, FL, 33126). *Bull Cancer (Paris)* 65(3): 365; 1978.

Data concerning the use of nitrate fertilizers in Chilean provinces having high and low incidences of stomach carcinoma are presented. Between 1945 and 1969, provinces with the highest incidences of stomach cancer also used the greatest amounts of nitrate fertilizers, while provinces with the lowest rates used the least amounts. (6 refs)

- 79-0543 Schistosomiasis Japonica (Katayama's Disease) and Cancer of the Gastrointestinal Tract, with Special Reference to the Presence of the Fluke Egg and Cancer Development.** (Jpn) Okamoto, T. (Fukuyama Natl. Hosp., Fukuyama-shi, Hiroshima Prefecture 720, Japan). *Gan No Rinsho* 24(8): 761-765; 1978.

Among 40 patients with schistosomiasis japonica (Katayama's disease) detected at the Fukuoka National Hospital, Japan, from 1962 to 1977, 21 also had cancer of the gastrointestinal tract (17 had stomach cancer, 4 intestinal cancer). Fourteen of the stomach cancers and all four intestinal cancers (which arose in papillae (2), sigmoid colon (1), and rectum (1)) were well-differentiated papillotubular adenocarcinomas. Fluke eggs were detected in tumor tissues in 10 of the stomach cancers and 3 of the intestinal cancers; 11 of these 13 tumors were well-differentiated papillotubular adenocarcinomas. In some patients intestinal metaplasia was recognized in the fluke-egg-containing gastric mucosa in the vicinity of the tumor. Benign elevated lesions (polyps and atypical epithelium) were observed in the stomach of 9 patients and in the large intestine of 5 patients. Malignant transformation of these benign lesions was seen in some cases. The results suggest that the gastrointestinal cancers developed in

the following steps: (1) presence of fluke eggs in gastrointestinal mucosa, (2) benign elevated lesions (polyps and atypical epithelium) and, (3) cancer. (14 refs)

- 79-0544 Cancer and "Cancer Related" Colorectal Lesions in Sao Paulo, Brazil.** (Eng) Marigo, C. (Dept. Pathology, Faculty Medical Sciences, Santa Casa Hosp., Sao Paulo, Brazil); Correa, P.; Haenszel, W. *Int J Cancer* 22(6): 645-654; 1978.

A series of 832 large bowel necropsy specimens collected in Sao Paulo, Brazil during 1973-75 were studied for the presence of colon diseases, particularly polyps, and analyzed in comparison with 5 other studied populations. Of 403 male specimens, hyperplastic polyps (HP) were found in 86, adenomatous polyps (AP) in 52, and juvenile polyps in 9. Analogous figures for 429 female specimens were 73, 52, and 9. Size and prevalence of both polyp types increased with age in both sexes. Length of colon correlated positively with risk of developing either AP or HP in this population, and the number of HP/specimen was greater than the number of AP/specimen. AP were primarily located in the ascending colon (24% of total), while the majority of HP (55%) occurred in the rectum. Racial differences were found, as the prevalence of AP in whites and blacks, respectively, was 15.6% and 9.4%, and the prevalence of HP, 26.0% and 15.6%. Furthermore, blacks did not show the predominance of AP in the proximal segments of the colon that was seen in whites. Carcinomas tended to concentrate in the descending colon and rectum, and this correlated positively with the location of HP. When compared with other colonic diseases, positive correlations were noted among the four conditions of AP, HP, diverticulosis, and hemorrhoids. Schistosomiasis did not show a significant relationship to polyps; and a consistently negative correlation was noted between AP, on the one hand and appendectomy, appendicitis, diverticulosis, and lymphoid hyperplasia on the other. These relationships are consistent with current hypotheses claiming a protective role of dietary fiber against carcinogenesis in the colon. (45 refs)

- 79-0545 Incidence of Malignant Tumors of the Stomach, Colon, Rectum and Lung and Incidence in Autopsy Material: 1900-1975, Heidelberg Area.** (Ger) Kayser, K. (Pathologisches Institut der Universitat, Im Neuenheimer Feld 220/221, D-6900 Heidelberg, W. Germany); Burkhardt, H. U.; Boschmann, W. *Virchows Arch Pathol Anat Histol* 380(2): 163-175; 1978.

A method for estimating the incidence of stomach, colon, rectum, and lung cancer from the incidences found at autopsy at the University of Heidelberg from 1900 to 1975 is described. Analysis showed that the percentage of autopsy cases has not changed significantly during this time. It was found that the incidence of stomach cancer has remained nearly constant, that of colon and rectal cancer has increased steadily,

and that of lung cancer has increased significantly since 1900. (24 refs)

- 79-0546 Autoradiographic Cytokinetics of Colonic Mucosal Hyperplasia in Mice.** (Eng) Barthold, S. W. (Section Comparative Medicine, Yale Univ. Sch. Medicine, New Haven, CT, 06510). *Cancer Res* 39(1): 24-29; 1979.

The cytokinetics of a naturally occurring hyperplastic disease of the colon in mice was determined by autoradiography and compared to kinetic changes seen by others in nonneoplastic and neoplastic colonic disease. Cell cycle parameters were determined by the fraction-labeled mitosis method. Labeling index, labeling pattern, and migration rates were also evaluated. During colonic hyperplasia, there was an increase in the variation of DNA synthesis times, resulting in prolongation of the S phase. The total cell cycle time and the G₁ phase were also prolonged. In addition, the labeling index was increased twofold, the proliferative zone was extended to include the entire crypt column and surface mucosa, and the migration rate was accelerated. These findings parallel the "atypical" cytokinetics found in human and murine neoplastic and preneoplastic disorders of the colon and may be a typical proliferative response of the mucosa to a variety of stimuli. (56 refs)

- 79-0547 The Regional Registry of Gastro-intestinal Cancer North Baden (2.2 Million Inhabitants).** (Eng) Kayser, K. (Pathologisches Institut der Universitat, Im Neuenheimer Feld 220/221, W. Germany); Burkhardt, H. U.; Jacob, W. *Virchows Arch Pathol Anat Histol* 380(2): 155-162; 1978.

The advantages, disadvantages, and experience gained from the regional gastrointestinal cancer registry in North Baden, West Germany, which is based only on histopathological data obtained from various local pathological institutes, are described. In addition, the incidences of gastrointestinal cancer in North Baden (population, 2.2 million) for the years 1971-1975 are tabulated. (16 refs)

- 79-0548 Malignant Neoplasm in Peutz-Jeghers Syndrome (2 Letters to Editor).** (Eng) Major, P. (Sidney Farber Cancer Inst., Charles A. Dana Cancer Center, Boston, MA); Ryo, U. Y. *JAMA* 240(20): 2155; 1978.

A previous conclusion that the rate of malignant transformation in Peutz-Jeghers polyps is 2%-3% is inaccurate; the 2%-3% incidence of malignancy in this syndrome refers to all digestive cancers and not only to those developing in the polyps. In a reply, it is stated that the origin of malignant neoplasms in the syndrome is difficult to document since not all polyps and tumors are given a thorough histologic exam and interpretation of the findings is subjective. (6 refs)

- 79-0549 Noncancer Deaths in Cancer and Noncancer Lineages.** (Eng) Albert, S. (Michigan Cancer Foundation, 110 East Warren Ave., Detroit, MI, 48201); Child, M. A.; Belle, S. *Am J Epidemiol* 108(5): 373-376; 1978.

To investigate whether a lineage in which at least one cancer was reported has a higher mortality in its noncancer members than does a lineage which has no cancer, family health histories of 2,411 female milk donors in a viral cancer study were collected. A lineage was defined as the parents and siblings of a parent of a subject. All together, 4,635 useable lineages of 4,822 potential lineages and 31,939 individuals were obtained for evaluation. A cancer lineage was defined as one in which at least one member was diagnosed as having cancer. Noncancer death rates were computed and expressed as deaths/100,000 person-years of exposure. Expected death rates in cancer lineages were calculated on the basis of the overall death rate in the entire population. There were 1,580 cancer lineages, of which 1,229 had only one cancer in the lineage. In all age groups of females except 45-49 yr, the noncancer death rate in the cancer lineage was significantly higher than in the noncancer lineage. Likewise, all male groups from cancer lineages, except those aged 35-44, had significantly higher noncancer death rates than did individuals from noncancer lineages. Although this study does not differentiate between the various possible noncancer causes of death, it indicates that cancer may be linked to other morbid conditions by either family heredity and/or family environment. (5 refs)

- 79-0550 Cancer Morbidity and Mortality Among the Insured Population of the Social Security Institute of Antioquia, Columbia.** (Eng) de Restrepo, H. E. (Instituto Colombiano de Seguro Social, Caja de Antioquia, Medellin, Columbia); Argemiro Franco, H. *Int J Epidemiol* 7(3): 285-291; 1978.

Information related to cancer cases diagnosed between 1968 and 1972 in Antioquia, Columbia, is reported. The crude annual incidence rates (per 100,000) for all cancers were 114.2/100,000 for men and 114.3/100,000 for women. The age-adjusted incidence rates (15 yr and over) for all cancers were 190.4 for men and 174.7 for women. The incidence of cancer in women exceeded that in men up to age 55, mainly due to the high rate of genital cancer in young women. The crude annual mortality rates from cancer were 42.6/100,000 for men and 38.0/100,000 for women. Skin, lung and stomach cancer predominated in men, and skin, cervix in situ, and breast cancer predominated in women. The high skin cancer rate presumably reflects exposure to the tropical sun. The incidence of cancer of the colon was typical of that found in Latin America. However, there was a colon/rectum ratio of 0.9 in men and 4.0 in women. (9 refs)

- 79-0551 Insect Damage, *Aspergillus flavus* Ear Mold, and Aflatoxin Contamination in South Georgia**

Corn Fields in 1977. (Eng) McMillian, W. W. (Univ. Georgia Coll. Agricultural Experimental Station., Tifton, GA, 31594); Wilson, D. M.; Widstrom, N. W. *J Environ Qual* 7(4): 564-566; 1978.

A survey of preharvest corn (*Zea mays* L.) in 31 counties in the coastal plain region of Georgia suggested that ears mold-
ed by *Aspergillus* spp. of the *Aspergillus flavus* group and ears damaged by insects were widespread in about 2 million acres of corn grown in the area. Ninety percent of the field-collected samples contained aflatoxin in excess of 20 µg/kg. Average ear damage by insects ranged from a low of 1.4 cm to a high of 8.9 cm. Highly significant correlations were found between insect damage and percentage of ears with visible *A. flavus* ear mold, between insect damage and aflatoxin contamination, and between percentage of ears with viable *A. flavus* ear mold and aflatoxin contamination. (12 refs)

- 79-0552 Mycotoxins in Food and the Variations in Tumor Incidence among Laboratory Rodents.** (Eng) Schoental, R. (Dept. Pathology, Royal Veterinary Coll., London, NW1 0TU, England). *Nutr and Cancer* 1(1): 13-14; 1978.

The variations in tumor incidence in the same animal species at various laboratories or even at the same laboratory at different times may be due to occasional contamination of the animal diet with mycotoxins, ie, the carcinogenic T-2 toxin, one of the irritant trichothecenes produced by *Fusarium* species, and/or the estrogenic compound zearalenone. The low fertility of *Praomys* noted at two laboratories might have been due to the presence of high concentrations of mold-derived estrogenic substances in the diet. Examples are given of the varied incidence of spontaneous stomach cancer in the South African rodent, *Praomys natalensis*, and of the varied incidence of a wide spectrum of tumors in BDX rats. The spontaneous tumors in rats, including those found in BDX rats, have been reported to resemble human cancers. This is not surprising in view of the possibility that similar mycotoxins may occasionally be present in human foodstuffs. Thus, some spontaneous tumors in animals and humans may have a common etiological factor; ie, mycotoxins. (21 refs)

- 79-0553 Excretion of Aflatoxin in the Urine of Normal Individuals and Patients with Liver Diseases in Ibadan (Nigeria).** (Eng) Bababunmi, E. A. (Dept. Biochemistry, Univ. Ibadan, Ibadan, Nigeria). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1729-1736; 1978.

Urinary aflatoxin (AF) levels were assayed in three groups

of adult men living in Ibadan, Nigeria: (1) normal healthy individuals selected from different socioeconomic classes, (2) hospitalized patients with liver diseases (hepatitis, cirrhosis, hepatoma), and (3) hospitalized patients without liver disease. At least 9/10 persons in each group excreted aflatoxin B₁ (AFB₁). Aflatoxin M₁, a metabolite of AFB₁, was identified in the urine of all persons tested. Group 1 men excreted 0.2-0.7 mg AF/24-hr output of urine. In Group 2, there was considerable individual variation of AF excretion, but the mean value of 2.7 mg was higher than that of Group 1 by a factor of at least 40. The mean excretion of AF by Group 3 was not significantly different from that of Group 1. The fact that free AFB₁ and a hydroxylated metabolite were present in the urine of all three groups suggests that AF poisoning could be a major factor in the etiology of primary liver cancer in many African countries. (12 refs)

79-0554 Hepatitis B and Primary Hepatocellular Carcinoma in a European Population. (Eng) Tri-chopoulos, D. (Dept. Hygiene and Epidemiology, Univ. Athens Medical Sch., Athens, Greece); Gerety, R. J.; Sparros, L.; Tabor, E.; Xirouchaki, E.; Munoz, N. *Lancet* 2(8102): 1217-1219; 1978.

The prevalence of serological markers of active or past hepatitis B virus (HBV) infection was determined in 80 Greek patients with primary hepatocellular carcinoma (PHC), 160 age- and sex-matched controls, and 40 patients with metastatic liver cancer (MLC). The relative risk (RR) of the various patterns of HBV serological markers for PHC was calculated. Active HBV infection, indicated by positive tests for HBV surface antigen (HBsAg) or antibody to the virus-B core antigen (anti-HBc) without antibody to HBsAg (anti-HBs), was associated with PHC (RR 10.4) but not with MLC (RR 1.2). Patients without markers and those who had recovered from virus infection B (anti-HBs-positive) had the same low risk for PHC (RR 0.8). Active infection was more common in PHC patients with coexisting cirrhosis than in those without cirrhosis (67% vs 26%). Thus, the relationship between active HBV and PHC seen in African and Asian populations was demonstrated in a European Caucasian population subject to different environmental and dietary factors. (26 refs)

79-0555 Link Between Hepatoma and Hepatitis B (Letter to Editor). (Eng) Peters, R. L. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA); Omata, M.; Ashcava, M. *Br Med J* 2(6150): 1502; 1978.

Patients with alcoholic cirrhosis and hepatocellular carcinoma (HCC) and those with nonalcoholic hepatitis B-viral cirrhosis and HCC should be studied separately, as an inverse relationship was found between racial groups with a high occurrence of HCC in alcoholic cirrhosis and racial groups with a high occurrence of HCC in hepatitis B-viral cirrhosis.

It is likely that differences in the frequency of occurrence of HCC in various geographical areas are related to differences in the incidence of chronic hepatitis B-viral disease and, perhaps, the time in life at which hepatitis B virus was acquired. (4 refs)

79-0556 Hepatocellular Carcinoma in Great Britain: Influence of Age, Sex, HBsAg Status, and Aetiology of Underlying Cirrhosis. (Eng) Johnson, P. J. (Liver Unit, King's Coll. Hosp., Medical Sch., London, England); Krasner, N.; Portmann, B.; Eddleston, A. L.; Williams, R. *Gut* 19(11): 1022-1026; 1978.

The influence of age, sex, hepatitis B surface antigen (HBsAg) status, and etiology of underlying cirrhosis on the frequency of hepatocellular carcinoma was examined in 294 patients who had died of cirrhosis. Hepatocellular carcinoma had been detected in 71/294 patients either during life or at necropsy. Patients with hemochromatosis and HBsAg-positive chronic active hepatitis (CAH) had a high incidence of tumor development (36% and 42%, respectively), whereas those with HBsAg-negative CAH and primary biliary cirrhosis had low incidences (11% and 3%, respectively). Patients with alcoholic or cryptogenic cirrhosis formed an intermediate group with respect to tumor incidence (25% and 27%, respectively). While the male:female ratio for the whole cirrhotic group was 2:1, the male:female ratio for those patients developing a tumor was 11:1. The groups with the highest percentage of men (hemochromatosis and antigen-positive CAH groups) had the highest frequency of tumor development. The influence of HBsAg was largely accounted for by the known predisposition of males to carry HBsAg. Age was the only other significant factor, malignant change occurring more commonly in those > 50 yr old than those < 50 yr old (30% and 7% respectively). In a group of 25 patients who had developed hepatocellular carcinoma without cirrhosis, the age distribution was younger and bimodal, and the male:female ratio was 1.1:1. Of 12 women patients in this group, four had taken oral contraceptives. There appeared to be a high incidence of cancer in the families of patients without cirrhosis, which may suggest an underlying genetic factor. (27 refs)

79-0557 Thyroid Cancer in Connecticut, 1935-1975; The Changing Distribution of Histologic Types over Time (Meeting Abstract). (Eng) Mendelsohn, L. S. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014); Meigs, J. W. *Am J Epidemiol* 108(3): 233; 1978. (no refs)

79-0558 Malignant Lymphoma Occurring in Kagoshima Prefecture, Japan: Pathological and Descriptive Epidemiological Survey Based on 849 Biopsy Materials. (Eng) Tokunaga, M. (Second Dept. Pathology, Faculty

Medicine, Kagoshima Univ., 1208-1 Usuki-cho, Kagoshima 890, Japan); Sato, E.; Tanaka, S.; Sakai, N. *Gann* 69(5): 673-678; 1978.

An epidemiological and pathological analysis was made of 849 cases of malignant lymphoma (ML) that occurred in Kagoshima Prefecture, Japan, between 1965 and 1976. The age-adjusted incidence was 3.02/100,000 (4.40 for males and 2.15 for females) over the entire study period. The av annual age-adjusted incidence per 100,000 for each 4-yr subperiod was 1.97 for 1965-1968, 2.65 for 1969-1972, and 3.38 for 1973-1976. The incidence also increased steadily with age, but the male/female ratio of 1.67 remained relatively constant. Nodal lymphomas were found in 604/789 usable tissue specimens, and they consisted of 56 Hodgkin's disease, 428 diffuse lymphomas, and 120 nodular lymphomas. Extranodal lymphomas were noted in 185 cases, and they included 67 cutaneous, 46 gastrointestinal, and 34 nasopharyngeal lymphomas, and 38 extranodal lymphomas at other sites. It is suggested that special immunogenetic or etiological factors provoke T-cell malignancy in the people of this area, resulting in the high incidence of diffuse nodal lymphoma and cutaneous extranodal lymphoma. (19 refs)

79-0559 Childhood and Adult Acute Leukaemia in Johannesburg Blacks. (Eng) Kusman, B. (Dept. Ophthalmology, Univ. Florida, Gainesville, FL); Jacobson, R. J.; MacDougall, L. G. *S Afr Med J* 54(24): 1007-1010; 1978.

The diagnosis, treatment, and follow-up of 34 black patients with acute leukemia seen at two Johannesburg hospitals during 1973-75 are discussed. Among 14 children (8 male), there were 6 cases of acute lymphoblastic leukemia (ALL), 5 of acute myeloblastic leukemia (AML), and 1 case each of monocytic, progranulocytic, and undifferentiated stem cell leukemia. Among the 20 adults (11 male), there were 12 cases of AML, 4 cases of ALL, 2 of acute monocytic leukemia, and 1 each of acute undifferentiated stem-cell leukemia and acute erythroleukemia. Common presenting symptoms of children were severe anemia, joint and bone pain, fever and/or infection, and bleeding. The most prevalent adult symptoms included bleeding manifestations, hepatomegaly, lymphadenopathy, anemia, and generalized pain. Remission was achieved in AML by the iv administration of daunorubicin (1.5 mg/kg) and cytosine arabinoside (1.0 mg/kg) every 12 hr. ALL was treated with vincristine (2 mg/m² iv/wk) and prednisone (40 mg/m² po for 3 wk); if remission did not occur, daunorubicin was added at 1.5 mg/kg/wt. Remission was initially achieved in 9/10 patients with ALL; at 36 mo, 2 children are known to be surviving in remission. Less favorably, 12/17 patients with AML achieved at least partial remission, and 3 adults are known to be alive at 10-18 mo. The emergence of acute leukemia in the young of this population conforms to the pattern seen in western countries, although a larger population of the cases were myelomonocytic than is usually seen in the western countries. (17 refs)

79-0560 BCG Vaccination and Leukemia. Epidemiological Investigations of the Influence of BCG Vaccination on Leukemia. (Ger) Ambrosch, F. (Institut für Spezifische Prophylaxe und Tropenmedizin, Kinderspitalgasse 15, A-1095 Vienna, Austria); Wiedermann, G.; Krepler, P.; Kundi, M. *Fortschr Med* 96(44): 2231-2242; 1978.

The rate of BCG vaccination of newborns and leukemia mortality during 1964-1975 in Austria were studied. After elimination of the mortality-reducing effect of improved therapy, a significant inverse correlation was found between the BCG vaccination rate and leukemia mortality in the age group 0-5 yr. From this correlation, a protection rate of 0.77 was calculated. The findings indicate the existence of a highly probable protective effect of BCG vaccination against leukemia. It will be necessary to study the relationship between BCG vaccination rate and leukemia incidence to verify this protective effect. (30 refs)

79-0561 Characteristics of Mothers at High Risk of Leukemia Developing in Their Children. (Eng) McCrea Curnen, M. G. (Div. Epidemiology, Columbia Univ. Sch. Public Health, New York, NY); Turgeon, L.; Flannery, J. T.; Varma, A. A. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 991-997; 1977.

The possible relationship between maternal age and birth order and childhood leukemia was investigated in a cross-sectional study of 389 children with leukemia between 1946 and 1964 and in a maternal birth cohort study of 500 children. In both studies, leukemia rates were higher in children born of mothers <20 yr old (Group A) than in those born of mothers ≥20 yr old (Group B). In the cross-sectional study, the rate of 74/100,000 live births in Group A mothers obtained in the first period of the study (1946-1954) was significantly higher than that in the older mothers (p < 0.02). The incidence of leukemia was unaffected by birth order in either period. Although in the cohort analysis, leukemia rates by year of birth of the mother and by age group at delivery were also higher for Group A mothers, this finding did not carry over when women of the same cohort delivered at older ages. The follow-up is still incomplete, however, so a cohort phenomenon cannot as yet be definitely excluded. The finding that Group A mothers are more at risk than older mothers to bear a child who will develop leukemia is compatible with the hypothesis that these very young mothers are also most likely to be susceptible to infectious agents. 79-0562 Incidence of Leukaemia and Allied Disorders in Western Australian World War II Ex-Servicemen. (Eng) Davies, I. H. (1 Kanimbla Road, Nedlands, West-

ern Australia 6009, Australia). *Med J Aust* 2(7): 321-322; 1978.

A survey of the Leukemia Registry of the Cancer Council of Western Australia revealed an increased incidence (during 1960-1969) of leukemia and allied disorders among World War II veterans with overseas and tropical area service (OTAS), compared with those who served only in temperate Australia (2.7/1,000 vs 1.05/1,000). Specifically, OTAS was associated with an excess of lymphosarcoma, Hodgkin's disease, follicular lymphoma, multiple myeloma, polycythemia vera, acute myeloid leukemia, and acute and chronic lymphatic leukemia. Possible etiologic factors in the increased incidence are considered to be malaria, drugs (ie, mepacrine), and nitrates or nitrites in canned food. (9 refs)

79-0566 Background Radiation Dose and Leukemia Mortality in North Japan. (Jpn) Sakka, M. (Tohoku Univ. Sch. Medicine, Tohoku, Japan). *Nippon Acta Radiol* 38(7): 702-706; 1978.

The relation of natural background radiation dose rate and leukemia death rate was examined in seven prefectures in north Japan, a region in which the natural environment as well as socioeconomic status are similar for all inhabitants. In the last 10 yr, more than 2,500 leukemia deaths were recorded, which were normally distributed throughout the entire area with a mean of 3.68 and a standard deviation (SD) of 1.14 deaths/10⁵ population/yr. There were no significant differences in the observed values of each prefecture in spite of the varied composition of the population. Natural background radiation dose rate had a normal distribution with a

mean of 8.98 μ R/hr and a SD of 2.12. The highest radiation dose rate in Niigata (10.44 μ R/hr) was significantly higher than the lowest in Aomori (6.48 μ R/hr) even through the leukemia death rates did not differ between these prefectures. The null hypothesis that a positive regression exists between dose rate and death rate even in the smallest dose range was not supported by this study. The leukemogenic effect of background radiation, if any, appears to be within a practical threshold. (23 refs)

79-0567 Temporal Distribution of Risk after Exposure. (Eng) Land, C. E. (NCI, Bethesda, MD, 20014); McGregor, D. H. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 831-843; 1977.

To investigate the latency of leukemia, lung cancer, and breast cancer among Japanese A-bomb survivors, the distributions of deaths and incident cases over time were compared between low-exposure (nonexposed and exposed with 0-9 rads) and high-exposure (100+ rads) groups by age at the time of the bomb (ATB). Results confirmed previous data that had shown leukemia to have a significantly shorter latency period in heavily exposed individuals compared with lightly exposed individuals who were < 50 yr ATB but not for those \geq yr ATB. Both low-dose and high-dose lung-cancer deaths occurred in substantial numbers only among those aged over 34 yr ATB. No breast cancer cases were found among those exposed to A-bomb radiation before age 10 yr, but extremely high rates were found in the high-dose group for the 10-19 yr and 20-34 yr ATB cohorts. Although lung cancer mortality and breast cancer incidence were higher in heavily exposed compared with lightly exposed individuals, latency periods for these were similar in both groups. Taken together, this evidence implies a difference in the causation of these malignancies: leukemias may have been solely the result of A-bomb radiation, while lung and breast cancer may have been the result of radiation followed by other, age-related exposures. 79-0568 Cancer Mortality and Incidence in Males in Los Alamos County, New Mexico (Meeting Abstract). (Eng) Voelz, G. L. (MS-404, Health Div., Los Alamos Scientific Lab., Los Alamos, NM, 87545); Stebbings, J. H.; Haxton, L. K. *Health Phys* 35(6): 916; 1978. (no refs)

79-0569 Descriptive Epidemiology of Cancer of the Larynx in the Province of Torino, Italy. (Eng) Terracini, B. (Istituto di Anatomia e Istologia Patologica, Via

Santena 7, 10126 Turin, Italy); Anglesio, E.; Panero, M.; Vineis, P. *Tumori* 64(5): 445-456; 1978.

The geographical distribution of laryngeal cancer was studied in the province of Torino between 1965 and 1969, and its possible correlation with certain environmental factors was investigated. The age-standardized incidence rate of laryngeal cancer in men was 14.7/100,000/yr in the city of Torino and 8.4/100,000/yr in the remainder of the province. These rates are among the highest in Europe. To validate the methodology in the study of laryngeal cancer, the investigation was extended to bladder cancer and to cancer in children. When the 291 towns in the province were grouped according to total population number and to the extent of industrialization, no correlations were found between the incidences of bladder, laryngeal, or infantile cancer and population number. However, the incidence of laryngeal cancer in men in highly industrialized towns was 40.7/100,000/yr, while that in men living in poorly industrialized towns was only 17.9/100,000/yr. Bladder cancer was also correlated with industrialization, but cancer in children was not correlated with either population number or industrialization. (21 refs)

79-0570 Negligible Role of Alcohol and Tobacco in the Etiology of Esophageal Cancer in Iran--A Case Control Study. (Eng) Mahboubi, E. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NB); Day, N. E.; Ghadirian, P.; Salmasizadeh, S. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp; 1149-1159; 1977.

A case-control study was conducted to determine the influence of alcohol, tobacco, and opium use on esophageal cancer (EC) in an area with a high EC incidence, the Caspian Littoral of Iran. In interviews with 151 patients and 301 healthy controls, alcohol consumption and smoking were found to be negligible. Regular opium use appeared to increase the cancer risk, but the possibility of bias in responses could not be excluded. It is suggested that the long-term nutritional deficiencies that exist in this region may be related to the increased risk of EC, without the added influence of tobacco or alcohol. These deficiencies are particularly severe among Turkomans. Since the present study failed to pinpoint any specific factor or known carcinogen, the combination and/or interaction of several factors may be involved in the etiology of EC. These factors include nutritional deficiency, trauma to esophageal mucosa through ingestion of dust and silica particles, consumption of hot beverages, and dietary constituents such as mycotoxins produced by fungi favored by environmental conditions and, possibly, extraneous carcinogenic seeds in wheat. (13 refs)

79-0571 Etiology and Epidemiology of Cancer of the Mouth and Pharynx in Switzerland. (Fre) Ju-

nod, B. (Institut universitaire de medecine speciale et preventive, Hopital Sandoz, CH-1011 Lausanne, Switzerland); Pasche, R. *Schweiz Med Wochenschr* 108(24): 882-887; 1978.

The epidemiology and etiology of cancer of the mouth and pharynx in Switzerland were studied. The incidence is 6.4/100,000, which is considerably higher than in most other industrialized countries (1.4-4.9/100,000), but significantly lower than in France (13.1/100,000). The male/female ratio is 7.4, which is comparable to that in countries with high overall incidence. Cancers of these sites mostly affect relatively young men. An etiological survey of 226 patients revealed a correlation between cigarette smoking and alcohol consumption on one hand, and the incidence of cancer of the mouth and pharynx on the other hand. Smokers smoking ≥ 10 cigarettes a day accounted for 87.9% of the 226 patients, while nonsmokers accounted for 6.8% only. Persons consuming ≥ 5 deciliters of wine daily accounted for 82% of the 226 patients. The cancer incidence was highest among smokers who were also heavy drinkers. While ethanol proper is not carcinogenic, it facilitates the penetration of carcinogenic substances through the mucosa. It seems likely that some alcoholic beverages available in Switzerland contain carcinogenic substances. The findings suggest that the beverages consumed by the cancer patients and those consumed by controls should be tested for mutagenicity. (32 refs)

79-0572 Prospective Studies on Cancer Epidemiology Based on Census Population in Japan. (Eng) Hirayama, T. (Epidemiology Div., Natl. Cancer Center Res. Inst., Tokyo, Japan). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp; 1139-1148; 1977.

The 9-yr follow-up results of a Japanese prospective study on the health consequences of cigarette smoking and alcohol consumption are presented. Among the 265,118 adults (aged ≥ 40 yr) studied, there was a total of 24,668 deaths, 6,485 from cancer. Men and women who smoked cigarettes daily had the highest death rates from cancer, and the risk was particularly high when smoking was initiated during adolescence. Smoking significantly increased the risk of cancer of all sites, the risk of cancer of the mouth, pharynx, esophagus, stomach, liver, pancreas, larynx, and lungs in men, and the risk of cancer of the mouth, stomach, liver, larynx, and lungs in women. Daily alcohol consumption enhanced the risk of cancer of the mouth, pharynx, esophagus, liver, and lungs in men and cancer of the esophagus and lungs in women. The risk among occasional drinkers was nearly identical to that of nondrinkers. Among individuals who were both smokers and drinkers, there was an elevated risk for digestive tract cancers, including cancer of the mouth, pharynx, esophagus, and liver. The risk of laryngeal and lung cancer was enhanced by smoking, regardless of drinking habits, but the risk of

digestive tract cancers was selectively high when smoking and drinking were combined. Thus, the oncogenicity of cigarette smoking in the larynx and lung differs from that in the digestive tract. It is suggested that the former represents contact carcinogenesis and the latter metabolic carcinogenesis. (3 refs)

79-0573 Cancer Mortality Among Carpenters in Hawaii.

(Eng) Budy, A. M. (Pacific Biomedical Res. Center, Univ. Hawaii, Honolulu, Hawaii, 96822); Rashad, M. N. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part I): 1193 pp.; 901-913; 1977.

Leukemia and lung cancer mortality in carpenters in Hawaii was compared before (1935-1969) and after (1970-1973) introduction of the use of water-soluble, copper-chrome-arsenates (arsenic acid and pentavalent arsenic compounds) as wood preservatives. Prior to 1970, FCAP (a preservative containing disodium arsenate) was used exclusively, with 1948-1951 representing the period of lowest exposure. Compared with a general population control group, the death rate among carpenters was significantly higher. Results also revealed an excess cancer death rate compared with controls, which was consistent during both usage periods (1935-1969 and 1970-1973): the relative increase in risk for cancer death in carpenters was 2.15 for the early period and 2.29 for the later period. These results are in general agreement with previous studies that showed an excess of lung cancer and leukemia-lymphoma among individuals occupationally exposed to wood. (7 refs)

79-0574 A Survey of a Population Exposed to High Concentrations of Arsenic in Well Water in Fairbanks, Alaska. (Eng) Harrington, J. M. (Center Disease Control, Atlanta, GA, 30333); Middaugh, J. P.; Morse, D. L.; Housworth, J. *Am J Epidemiol* 108(5): 377-385; 1978.

An epidemiologic study of 211 persons exposed to high arsenic concentrations (up to 10,000 $\mu\text{g/l}$) in their well water was carried out to assess exposure, absorption, and clinical sequelae of chronic arsenic ingestion. In well-water drinkers, close correlations were found between well water arsenic levels and urinary arsenic and between well water arsenic levels and hair arsenic levels. Nail arsenic levels correlated poorly with water arsenic exposure. No clinical or hematologic abnormalities were found. (23 refs)

79-0575 Asbestos-associated Disease in United States Shipyards. (Eng) Selikoff, I. J. (Environmental Sciences Lab., Mount Sinai Sch. Medicine, City Univ. New

York, New York, NY); Hammond, E. C. *CA* 28(2): 87-99; 1978.

Data are presented on asbestos-associated diseases among US, Canadian, British, and French shipyard workers. In a group of 1,117 asbestos insulation workers in the New York area, most with >20 yr exposure had abnormal x-rays and most lung cancers, including mesothelioma, occurred after 30 yr. Of 1,000 Groton, Connecticut, shipyard workers, one-half showed x-ray evidence of pulmonary or pleural changes indicative of asbestosis. Parenchymal disease was present in 36.8% and pleural changes in 29.7% of 364 workers with ≥ 20 yr exposure. The high proportion of asbestotic x-ray changes suggests an increased future risk of asbestos-associated neoplasms, which include lung cancer, pleural or peritoneal mesothelioma, and esophageal, gastric, colorectal, oropharyngeal, laryngeal, and renal cancer. Recommendations for ameliorating the hazards of asbestos exposure are outlined. (19 refs)

79-0578 Lung Cancer in New Caledonia, A Nickel Smelting Island. (Eng) Lessard, R. (Sch. Public Health, Univ. Michigan, Ann Arbor, MI); Reed, D.; Maheux, B.; Lambert, J. *J Occup Med* 20(12): 815-817; 1978.

The occurrence of lung cancer in New Caledonia during 1970-1974 and its possible association with nickel refining were studied. Ninety-two cases of lung cancer were diagnosed in this period. The av annual age-adjusted incidence rate was approx seven times higher in men than in women. The total incidence rate for all men living in Noumea, the capital city and the site of the Ni smelter, was higher (53) than the rate for all rural men (34). However, there was no consistent pattern among racial groups. These incidence rates were three to six times higher than those in 5/6 other South and Central Pacific countries investigated, and they were similar to rates in industrialized countries. There was a significant inverse relationship between av annual incidence rate and distance of residence from the smelter. The association of lung cancer, smoking, and Ni occupation was analyzed in 68/81 male patients for whom this information was available. Lung cancer and Ni occupation were significantly associated independently of the effects of age and cigarette smoking [relative risk (RR), 3.0]. Lung cancer and cigarette smoking were significantly associated independently of the effects of age and Ni occupation (RR, 22). There was no significant interaction

between cigarette smoking and Ni occupation that would increase the RR of each variable separately. (16 refs)

- 79-0579 Oat Cell Lung Cancer in Selected Occupations. A Case-Control Study.** (Eng) Wegman, D. H. (Dept. Labor and Industries, Div. Occupational Hygiene, Commonwealth Massachusetts, Executive Office Manpower Affairs, 39 Boylston St., Boston, MA, 02116); Peters, J. M. *J Occup Med* 20(12): 793-796; 1978.

A case-control study was made to evaluate reported occupation in 91 men with oat cell cancer of the lung identified in the Massachusetts Tumor Registry between 1965 and 1972. The patients were matched for age at diagnosis (limit, 60 yr) and reporting hospital with 91 CNS cancer patients also obtained from the registry, and the two groups were compared with respect to occupation and smoking history, ascertained by investigation of tumor registry form, death certificate, medical record, and interview information, which was obtainable in 71% of cases plus controls. The mean age at diagnosis was 52 yr for both cases and controls. Eight cases had been transportation equipment operators vs one control, and the mean age of these cases was the lowest among all cases and was 4 yr below that of the control in this occupation (46 vs 50). Fourteen cases were classified as laborers vs only 3 controls, but a more specific investigation as to type of labor did not reveal any particular pattern. Blind reevaluation of occupation reclassified four men in transportation-related industries as transportation equipment operators, and all four were subsequently identified to be cases. Cigarette smokers comprised 94% of cases and 77% of controls for whom this information could be determined. These results are consistent with the hypothesis that an excess risk of lung cancer in transportation equipment operatives is related to chronic exposure to engine exhaust. (18 refs)

- 79-0580 Investigation of Possible Association of Exposure to Nickel and Lung Cancer Mortality in Workers at an Aircraft Engine Factory (Meeting Abstract).** (Eng) Bernacki, E. J. (United Technologies, Inc., Hartford, CT); Parsons, G. E.; Sunderman, F. W. *Ann Clin Lab Sci* 8(6): 504; 1978. (no refs)

- 79-0581 Iatrogenic Carcinoma Induction by the Use of Tar Preparations in Dermatology.** (Ger) Gotz, H. (Dermatologische Klinik und Poliklinik, Universitat Essen, Hufelandstr. 55, 4300 Essen, W. Germany); Deichmann, B.; Zabel, M. *Z Hautkr* 53(21): 751-755; 1978.

Questionnaire replies obtained from 1,075 dermatologists in West Germany concerning the possible carcinogenic effect of dermatological tar and tar preparations are evaluated. Seventeen dermatologists observed precancerous lesions and one observed carcinoma in connection with the use of tar preparations, regardless of the exposure of the treated skin surface to UV light. Two of these 18 dermatologists gave no further

details, while 10 indicated occupational exposure to tar, and 2 reported precancerous lesions following treatment with tar preparations and arsenic. Only four dermatologists believed the precancerous lesions and carcinoma to have been caused by the use of dermatological tar preparations. The carcinoma or precancerous lesions that develop following long-term treatment of chronic dermatoses with tar preparations, arsenic, x-rays, and exposure to UV light is an additive effect, in which it is impossible to determine contribution of the different etiological factors. (14 refs)

- 79-0582 40 Year Epidemiologic Evaluation of Salivary Neoplasia in Rochester, Minnesota (Meeting Abstract).** (Eng) Bouquot, J. (West Virginia Univ., Morgantown, WV, 26506); Lovested, S.; Weiland, L.; Kurland, L. *J Dent Res* 58(Special Issue A): 419; 1979. (no refs)

- 79-0583 The Use of Logistic Regression for Modelling Risk Factors: With Application to Non-melanoma Skin Cancer.** (Eng) Vitaliano, P. P. (Sch. Medicine, Univ. Washington, Seattle, WA, 98195). *Am J Epidemiol* 108(5): 402-414; 1978.

Logistic regression was used to estimate the relative risk of basal and squamous skin cancer for factors such as cumulative lifetime solar exposure, age, complexion, and "tannability". In contrast to previous studies, a subject's exposure to the sun was determined by interview data in this study, rather than by indirect means such as latitude or by the number of sun days in the subject's environment. A relatively new technique was used to estimate relative risk by controlling for confounding and testing for effect modification. A linear effect for the relative risk of cancer versus exposure was found. Tannability was shown to be a more important risk factor than complexion. This result is consistent with results obtained by a previous investigator. (22 refs)

79-0584 The Resolution of Membrane Proteins Based Upon Size, Charge, and Hydrophobicity. (Eng)

Fernandes, P. B. (Dept. Microbiology and Immunology, Temple Univ., Sch. Medicine, 3400 N. Broad St., Philadelphia, PA, 19140); Nardi, R. V.; Franklin, S. G. *Anal Biochem* 91(1): 101-114; 1978.

Membrane proteins from several strains of *Escherichia coli*, *Salmonella enteritidis*, and *Proteus mirabilis* were resolved with a polyacrylamide gel electrophoresis system based on the addition of the nonionic detergent Triton X-100 to acetic acid-urea polyacrylamide gels. The system allows the detection of microheterogeneity in histones involving the substitution of neutral residues, and it separates proteins on the basis of charge, size, and hydrophobicity. The optimal resolution conditions of 12 mM Triton and 8 M urea were determined by electrophoresis through transverse urea and Triton X-100 gradients. The system was successful not only in distinguishing different genera of gram-negative bacteria, but also in analyzing type and strain differences. A two dimensional method using Triton-urea-acetic acid gels in the first dimension and sodium dodecyl sulfate gels containing 15% acrylamide in the second dimension was able to resolve proteins that could not be conveniently resolved by either method individually. This system appears to provide a promising means for analyzing membrane envelope proteins that are due to missense mutations. (39 refs)

79-0585 Changes in Intramembranous Particle Topography and Concanavalin A Receptor Mobility Associated with Myoblast Differentiation. (Eng) Furcht, L. T.

(Dept. Lab. Medicine and Pathology, Univ. Minnesota, Medical Sch., Box 609 Mayo, Minneapolis, MN, 55455); Wendelschafer-Crabb, G. *Differentiation* 12(1): 39-45; 1978.

Two parameters of cell surface organization accompanying myoblast differentiation, ie, plasma membrane intramembranous particle (PMP) distribution and concanavalin A (con-A) receptor topography and redistribution, were examined by freeze-fracture techniques and by ultrastructural cytochemistry of L6 myoblasts, respectively. Undifferentiated mononucleated cells were seen to have a clustered distribution of PMP on the majority of the fracture faces. A more uniform PMP distribution was associated with cell differentiation and cell fusion. In undifferentiated or differentiated, glutaraldehyde-fixed cells reacted with con-A, a uniform con-A distribution was observed on the cell surfaces. In contrast, over 99% of unfixed, live, differentiated cells showed

a profound redistribution of the lectin, while receptors remained in a uniform array on 95% of the live, undifferentiated cells. In addition to the membrane binding, con-A was observed to bind to an extracellular filamentous matrix seen in high-density, undifferentiated cultures, which then appeared to be degraded with differentiation and myoblast fusion. These studies show that a number of membrane changes, both structural and dynamic, occur with myoblast differentiation. (28 refs)

79-0586 Transport of DNA from Lymphocytes to Fibroblasts in Culture. (Eng) Harris, G. (Div. Experimental Pathology, Kennedy Inst. Rheumatology, Bute Gardens, London W6 7DW, England); Olsen, I.; Furner, P.

Differentiation 12(1): 1-13; 1978.

The transfer of radioactivity from labeled DNA of CBA mouse spleen lymphocytes to recipient hamster lung V79 fibroblasts was investigated. Lymphocytes were stimulated with 4 µg/ml Concanavalin A and incubated with (³H)-thymidine (2 µCi/ml, 5 µM), after which time 2 x 10⁶ of the labeled cells were added to 2 x 10⁵ fibroblasts. When added to V79 cells in logarithmic growth phase, autoradiography showed that all fibroblasts were labeled within 2 hr, and that > 50% of total radioactivity moved from donor to recipient cell nuclei in 6 hr. Although the rate of incorporation in confluent fibroblast cultures was slower, all these cells were labeled within 24 hr. When the labeled donor DNA, substituted with bromodeoxyuridine, was followed in recipient cells by buoyant density measurements in cesium chloride gradients, it associated with the nuclear DNA of the host fibroblasts. The donor DNA was not only broken down and its products reutilized for fresh DNA synthesis in the recipient cell, but relatively intact lymphocyte DNA was also incorporated. This intact DNA was retained in confluent recipient cell cultures for much longer periods than in actively growing fibroblast cultures. These results show that lymphocytes can be a source of macromolecular DNA for other cells, perhaps for transport of regulatory or informational molecules. (29 refs)

79-0588 Molecular Heterogeneity of DNA Polymerase α from P815 Mouse Mastocytoma Cells. (Eng) Bieri-Bonniot, F. (Pharmaceuticals Div., CIBA-Geigy Ltd., Basel, Switzerland); Schuerch, A. R. *FEBS Lett* 96(1): 192-196; 1978.

Data on the separation and partial analysis of two forms of DNA polymerase α from P815 mouse mastocytoma cells are presented, the two peaks of activity being distinguished by their affinity for poly(dT) on poly(dT)-CL-Sepharose columns. Both forms exhibited properties characteristic of DNA polymerases α (sensitivity to N-ethylmaleimide, dependency on dithiothreitol, molecular size range), but they differed in their relative ability to copy various synthetic templates, in the ionic conditions necessary to their max activity, and in the degree to which they are protected against heat inactivation by 5 mM dithiothreitol. One form migrated slightly faster than the other on glycerol gradients, possibly due to a difference in configuration or quaternary structure. It is concluded that there are differences in the molecular structure and properties of the two forms. (15 refs)

79-0589 Photoaffinity Labeling of the Ribosomal Peptidyl Transferase Site with Synthetic Puromycin Analogues. (Eng) Vince, R. (Dept. Medical Chemistry, Coll. Pharmacy, Univ. Minnesota, Minneapolis, MN, 55455); Brownell, J.; Fong, K. L. *Biochemistry* 17(25): 5489-5493; 1978.

The puromycin analog N ϵ -(2-nitro-4-azidophenyl)-L-lysiny puromycin aminonucleoside (NAP-Lys-Pan) was studied for its potential as a photoaffinity label in the peptidyl transferase center of 70S ribosomes. The analog was synthesized by a condensation reaction of N ϵ -tert-butyloxycarbonyllysine and 4-fluoro-2-nitrophenylazide, with coupling of the product to puromycin aminonucleoside followed by deblocking. The analog demonstrated excellent acceptor activity in the peptidyl transferase reaction, exhibiting an affinity for the acceptor (A) site (as indicated by Michaelis constants) only slightly lower than that of puromycin. Furthermore, its aryl azide group was capable of being decomposed by visible light. This photosensitivity was employed to link the analog covalently to *Escherichia coli* ribosomes, followed by a polyuridine direction of N-acetyl[14 C]-L-phenylalanyl-tRNA (Ac(14 C)-Phe-tRNA) to the peptidyl sites of the ribosomes. Subsequently, transpeptidation transferred Ac(14 C)Phe to the NAP-Lys-Pan in the A site with a labeling efficiency of 2.6%. When the ribosomes were dissociated into subunits by dialysis, scintillation counting indicated that the radioactivity was concentrated in the 50S subunit, in which the peptidyl

transferase center is located, confirming the specificity of labeling. (13 refs)

79-0590 γ -Glutamyl Transpeptidase and Malignant Transformation of Cultured Liver Cells. (Eng) Huberman, E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Montesano, R.; Drevon, C.; Kuroki, T.; St. Vincent, L.; Pugh, T. D.; Goldfarb, S. *Cancer Res* 39(1): 269-272; 1979.

The relationship between γ -glutamyl transpeptidase (GGT) and malignant cell transformation was analyzed in malignant and nonmalignant cultured epithelial cell lines derived from rat livers and fibroblastic cell lines derived from hamsters and mice. GGT activity was prominent (25% to 90% of cells) in 3/5 malignant epithelial liver cell lines. None of the nine fibroblastic or four nonmalignant epithelial cell lines exhibited GGT activity. These results suggest that by use of GGT activity, a significant fraction of spontaneously or chemically induced malignant cells can be detected in cultured liver cells. Thus, in conjunction with other markers, this marker may help in identifying tumorigenic cells in liver epithelial cultures. (30 refs)

79-0591 Ultrastructure of Elementary Chromatin Particles Studied by Surface-Spreading Whole-Mount Electron Microscopy. 79-0592 Inhibition of Growth of Transformed Cells and Tumors by an Endogenous Acceptor of Galactosyltransferase. (Eng) Podolsky, D. K. (Gastrointestinal Unit, Massachusetts General Hosp., Boston, MA, 02114); Weiser, M. M.; Isselbacher, K. J. *Proc Natl Acad Sci USA* 75(9): 4426-4430; 1978.

Investigation was made of the effect of a cancer-associated galactosyltransferase acceptor (CAGA), a glycopeptide purified from human malignant effusions, on cell growth in vitro and in vivo. CAGA (0.5-1.5 μ g/ml, 2 ml/dish) was added to cultures of normal and polyoma virus-transformed baby hamster kidney and NIL cells (BHK, NIL, BHKpy, and NILpy, respectively), human breast adenocarcinoma cells (BT-20), human pancreatic carcinoma cells, and Chang cells at the time of plating. CAGA inhibited attachment and growth of the transformed cells significantly but had minimal effects on nontransformed cells. Transformed hamster and

human malignant cells appeared more rounded and possessed both vacuolar and refractile inclusions and they were killed by as little as 0.5 $\mu\text{g/ml}$ CAGA, but nontransformed cells did not show a significant change in growth or morphology. Inoculation of hamsters with CAGA (20 μg sc or ip) at the time of their inoculation with BHKpy or BHKpygiv inhibited tumor growth 69%-94% by the sc route and 39%-67% by the ip route. Administration of CAGA after the development of a palpable tumor (approx 0.5 cm) reduced the growth rate 60%-85% and, in some cases, markedly reduced tumor wt and caused tumors to disappear. Thus, CAGA inhibits tumor growth in vitro and in vivo, but the mechanism of inhibition remains to be determined. (28 refs)

79-0597 Direct Resorption of Bone by Human Breast Cancer Cells In Vitro. (Eng) Eilon, G. (Dept. Medicine, Div. Endocrinology and Metabolism, Univ. Connecticut Health Center, Farmington, CT, 06032); Mundy, G. R. *Nature* 276(5689): 726-728; 1978.

The process by which human breast cancer cells resorb bone

was investigated in vitro. In three separate experiments, supernatants from cultures of the human breast cancer cell line MCF-7 caused the release of previously incorporated ^{45}Ca from live and dead fetal rat long bones. Similar results were obtained when the bones were cocultured with the MCF-7 cells. The bone matrix was also resorbed by the cells and their conditioned media. Supernatants from four other established breast cancer cell lines also caused mineral release from devitalized fetal rat bones, whereas other normal and neoplastic cells had no effect. The effects of MCF-7 cells on bone could not be ascribed to changes in pH. Bones cultured with prostaglandin E_2 (10^{-6} M) showed many giant multinucleated osteoclasts, whereas bones cultured with supernatants from the MCF-7 cultures showed no detectable osteoclasts. However, the increase in ^{45}Ca release observed in bones cultured with prostaglandin and those cultured with the cancer cells was similar (80% and 83% more than corresponding controls, respectively). Studies in which live bones were cultured with cortisol and phosphate, both of which inhibit the effects of osteoclasts on bone, confirmed that osteoclasts are not required for breast cancer cells to resorb bone. That bone resorption stimulated by MCF-7 cells occurs independently of prostaglandins was confirmed by culturing MCF-7 cells with indomethacin (10^{-5} M) on live bones; indomethacin had no effect on ^{45}Ca release. The results demonstrate that some cultured human breast cancer cells can resorb bone directly in vitro, independently of osteoclast stimulation. (20 refs)

79-0598 Totipotent Cells of Parthenogenetic Origin in a Chimaeric Mouse. (Eng) Stevens, L. C. (Jackson Lab., Bar Harbor, ME, 04609). *Nature* 276(5685): 266-267; 1978.

Evidence is given that early embryonic parthenogenetic (PG) mouse cells are totipotent: they can give rise to fully functional ova that, when fertilized by sperm, develop into normal individuals. PG four- and eight-cell embryos of the pigmented mouse strains LT/Sv and LTXBJ and their F_1 hybrids and embryos from normally fertilized eggs of albino strain 129/Sv and (129 x A/He) F_1 were flushed from the oviducts of superovulated females. The zona pellucida was removed, one normal and two PG embryos were aggregated, and 456 aggregated triplets were transferred to the uteri of 47 pseudopregnant (SJL x C57BL/10) F_1 females. Twenty-four offspring were produced, 6 (4 males, 2 females) of which were identified as chimeras by their partially pigmented coats and irises. All were mated with strain 129 mice. The four males sired 285 offspring, all albinos. One female produced 33 albino offspring, the other five litters of 29 albino offspring. Her sixth and last litter contained two albino and two pigmented offspring. The latter could only have been derived from ova of PG origin (LT) fertilized by normal albino (129) sperm. Increasing the number of cells in a PG embryo prolonged its survival in utero. Even though pure PG embryos will not survive in utero, these results demonstrate that their cells are capable of participating in normal development when as-

sociated with normal cells. The production of offspring with the *C* and *Hbb-s* (*s* = single) alleles from an aggregation chimera between a PG *C/C Hbb-s/Hbb-s* and a normal *c/c Hbb-d/Hbb-d* (*d* = diffuse) embryo demonstrates that fully functional totipotent ova of PG origin were produced. (12 refs)

79-0599 Use of the Beta-Binomial Distribution in Dominant-Lethal Testing for "Weak Mutagenic Activity". (Eng) Vuataz, L. (Mathematics Section, Nestle Products Technical Assistance Co. Ltd., CH1814 La Tour de Peilz, Switzerland); Sotek, J. *Mutat Res* 52(2): 211-230; 1978.

Computer simulations of dominant-lethal test experiments were performed to compare the behavior of the beta-binomial test with that of the traditional chi-square test on 2 x 2 frequency tables and to estimate the type I error rate. Three models were used: (1) the mating ratio is 1, and the probability (*p*) that an implant will die is distributed over the couples, (2) the mating ratio is > 1, and *p* is distributed over the males, the females mated to the same male being binomial observations of the value of *p* supplied by the male, and (3) the mating ratio is > 1, and *p* is distributed over the females. The av rates of dead implants for the treatment and control groups were 0.10 and 0.08, respectively, and significance level was 0.05. Although the chi-square test was applicable when *p* was constant in a group, the type I error rate increased from 0.05 to 0.30 when *p* was distributed over experimental units. The

beta-binomial simulation results, however, indicated an excellent overall fit of the model in each of the experimental groups. Av powers of 0.72 and 0.85 were reached for groups of 300 and 450 animals, respectively, when the increment in the rate of dead implants was 2%. It is recommended that for a given number of animals/group, a mating ratio larger than one should be used, and the males should be the considered experimental units. (8 refs)

79-0600 Ectopic Production of High Molecular Weight Calcitonin and Corticotropin by Human Small Cell Carcinoma Cells in Tissue Culture: Evidence for Separate Precursors. (Eng) Bertagna, X. Y. (Dept. Medicine, Vanderbilt Univ. Sch. Medicine, Nashville, TN, 37232); Nicholson, W. E.; Pettengill, O. S.; Sorenson, G. D.; Mount, C. D.; Orth, D. N. *J Clin Endocrinol Metab* 47(6): 1390-1393; 1978.

The presence of immunoreactive-calcitonin (IR-CT) in the ACTH-secreting DMS-79 continuous line of human small cell lung carcinoma cells was demonstrated. Two major and one minor high-mol wt forms of IR-CT were observed after gel exclusion chromatography under denaturing conditions. None of these IR-CT materials was extracted from DMS-79 medium by affinity chromatography using an ACTH antibody covalently bound to agarose. The results did not support the existence of a common CT/ACTH/ β -lipotropin/ β -endorphin precursor molecule. (13 refs)

Subject Index

Abnormalities

- Estradiol, 17-Ethynyl-
Transplacental Effect, Review, 79-0043
- 2-Imidazolidinethione
Transplacental Effect, Cat, 79-0214
- 4,4'-Stilbenediol, α, α' -Diethyl-
Dose-Response Study, Rat, 79-0307
- Genitalia, Male, Review, 79-0043
- Reproductive Organs, Rat, 79-0307
- Transplacental Effect, 79-0307
- Transplacental Effect, Review, 79-0043

Acetaldehyde, Chloro-

- Ames Test
Mutagenic Activity, 79-0125
- Bacillus subtilis*
Mutagenic Activity, 79-0125
- Microsomes, Liver
Ames Test, 79-0109

Acetaldehyde, Dichloro-

- Microsomes, Liver
Ames Test, 79-0109

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl- DNA

- Complex Formation, 79-0170
- Linear Dichroism, 79-0170
- Nucleic Acid Denaturation, 79-0170

Acetamide, *N*-Fluoren-2-yl-

- Acetohydroxamic Acid, *N*-Fluoren-2-yl-
Carcinogenic Metabolite, 79-0172
- Acytransferases
Ames Test, 79-0023
- Arylhydroxamic Acids, 79-0023
- Carcinogenic Activity, Review, 79-0023
- Ames Test
Wheat Sprout Extract, 79-0169
- Cell Division
Adrenal Glands, Liver, Rat, 79-0176
- DNA
Chromosome Aberrations, 79-0171
- Hepatoma
Aldehyde Oxidoreductases, 79-0175
- Immune Serums
Cell Division, 79-0176
- Growth Substances, 79-0176
- Mutagenic Activity
Liver Epithelial Cells, Rat, 79-0120
- Thioguanine Resistance, 79-0120
- Polyribosomes
Cell Adhesion, 79-0173
- Centrifugal Degranulation, 79-0173
- Liver, Rat, 79-0173
- Thymus Neoplasms
Retinol, 79-0300
- Thyroid Gland
Histological Study, Rat, 79-0177
- Liver Regeneration, 79-0177
- Mitosis, 79-0177

Acetamide, *N,N*-Fluorene-2,7-diylbis-

- Leukemia, Myelocytic
Carcinogenic Activity, Rat, 79-0174
- Histological Study, Rat Vertebrae, 79-0174

Acetamide, *N,N*-Fluorene-2,7-diylbis- (cont'd) Neoplasm Metastasis, 79-0174

Acetamide, *N*-Methyl-

- Glycine
Charge-Transfer Complex, 79-0168
- Peptide Bonds, 79-0168
- Glyoxal
Charge-Transfer Complex, 79-0168
- Peptide Bonds, 79-0168

Acetamide, Thio-

- Drosophila melanogaster*
Mutagenic Activity, 79-0166

Acetic Acid

- Benz(a)anthracene, 7,12-Dimethyl-
Croton Oil, 79-0261
- Skin Neoplasms
Benz(a)anthracene, 7,12-Dimethyl-, 79-0261

Acetic Acid, (4-Chloro-6-(2,3-xylidino)-2-pyrimidinylthio)- Hepatoma

- Acatasia, 79-0167
- Acetyltransferases, 79-0167
- Alpha Fetoproteins, 79-0167
- Carcinogenic Activity, Mouse, Rat, 79-0167

Acetic Acid, Chromium Salt

- Bacillus subtilis*
Mutagenic Activity, 79-0108
- Escherichia coli*
Mutagenic Activity, 79-0108
- Leukocytes
Chromosome Aberrations, 79-0108

Acetic Acid, (Ethylenedinitrilo)tetra-, Dicalcium Salt Lead

- Carcinogenic Activity, Review, 79-0054

Acetohydroxamic Acid, *N*-Fluoren-2-yl-

- Acetamide, *N*-Fluoren-2-yl-
Carcinogenic Metabolite, 79-0172
- Ames Test
Sulfation, 79-0172
- Wheat Sprout Extract, 79-0169
- Ascorbic Acid
Ames Test, 79-0172
- Hydroxylamine, *N*-Fluoren-2-yl-
Ames Test, 79-0172
- Lymphocytes
Chromatids, 79-0112
- Phosphoric Acid, Diethyl-, *p*-Nitrophenyl Ester
Ames Test, 79-0172

Acetone

- Propane, 2-Nitro-
Oxidoreductases, 79-0178

Acetonitrile

- Benz(c)acridine
Carcinogenic Activity, 79-0137

p-Acetophenetidide, *N*-Hydroxy-

- Ames Test
Mutagenic Activity, 79-0244
- Enzyme Activation
Mutagenic Activity, 79-0244

- p*-Acetophenetidine**
 Ames Test
 Mutagenic Activity, 79-0244
- Acetoxyphenacetin**
 see Hydroxylamine, *N,O*-Diacetyl-*N*-(*p*-ethoxyphenyl)-
- Acetyltransferases**
 Hepatoma
 Acetic Acid, (4-Chloro-6-(2,3-xylydino)-2-pyrimidinylthio)-, 79-0167
- Acridine**
 Guanyl Cyclase
 Liver, Rat, 79-0258
- Acridine, 3,6-Diamino-**
 DNA, Bacterial
 DNA Repair, 79-0386
Escherichia coli
 DNA Repair, 79-0386
 Ultraviolet Rays
 DNA, Bacterial, 79-0386
 DNA Repair, 79-0386
 Virus, Herpes Simplex
 Virus Activation, Review, 79-0068
 Virus, SV40
 Virus Activation, Review, 79-0068
- Acridine, 3,6-Diamino-, Sulfate**
 Chromatids
 DNA Replication, 79-0115
 Hypoxanthine Phosphoribosyltransferase
 Mutagenic Activity, 79-0115
- Acridine Mustard**
 Guanidine, 1-Methyl-3-nitro-1-nitroso-
 DNA Replication, 79-0226
 HeLa Cells
 DNA Replication, 79-0226
 Xeroderma Pigmentosum
 DNA Replication, 79-0226
- Acridinium, 3,6-Diamino-10-methyl-, Chloride**
Escherichia coli
 DNA Repair, 79-0329
 Ultraviolet Rays
Escherichia coli, 79-0329
- Acriflavine**
 see Acridinium, 3,6-Diamino-10-methyl-, Chloride
- Acrylamide, 2-(2-Furyl)-3-(5-nitro-2-furyl)-**
 Cells, Cultured
 Cell Transformation, Neoplastic, 79-0180
 Chromosome Aberrations, 79-0180
 Chromosome Aberrations
 Transplacental Carcinogenesis, 79-0180
 Methane, Sulfinylbis-
 Transplacental Carcinogenesis, 79-0180
 Mutagenic Activity
 Dose-Response Study, 79-0179
 Transplacental Carcinogenesis
 Dose-Response Study, Hamster, 79-0180
 Yeasts
 Mutagenic Activity, 79-0179
- Actinomycin D**
 DNA Replication
 Liver, Kidney, Mouse, 79-0250
- Acyltransferases**
 Acetamide, *N*-Fluoren-2-yl-
- Acyltransferases (cont'd)**
 Ames Test, 79-0023
 Arylhydroxamic Acids, 79-0023
 Carcinogenic Activity, Review, 79-0023
 Quinoline, 4-(Hydroxyamino)-, 1-Oxide
 Carcinogenic Activity, Review, 79-0023
- Adenine**
 Benzo(a)pyrene, 7,8-Dihydroxy-9,10-oxy-7,8,9,10-tetrahydro-
 DNA, Binding, Review, 79-0010
- Adenocarcinoma**
 Benzo(a)pyrene
 Food Contamination, 79-0289
 Breast Neoplasms
 Growth Inhibition, 79-0592
 Cervix Neoplasms
 Ultrastructural Study, 79-0525
 Colonic Neoplasms
 Hydrazine, 1,2-Dimethyl-, 79-0163
 Precancerous Conditions, Review, 79-0044
 Dimethylamine, *N*-Nitroso-
 Food Contamination, 79-0289
 Endometrial Hyperplasia
 Estrogenic Substances, Conjugated, 79-0534
 Forssman Antigen
 Antigen-Antibody Complex, 79-0493
 Gastrointestinal Neoplasms
 Schistosomiasis, 79-0543
 Glycosphingolipids
 Isoantigens, 79-0493
 Gynecologic Neoplasms
 Neoplasm Metastasis, 79-0523
 4,4'-Stilbenediol, α,α' -Diethyl-, 79-0027
 Isoantigens
 Antigen-Antibody Complex, 79-0493
 Kidney Neoplasms
 Epidemiology, Review, 79-0079
 Virus, Polyoma, BK, 79-0442
 Liver Neoplasms
 Benzenamine, *N,N*-Dimethyl-4-((3-methylphenyl)azo)-, 79-0239
 Diethylamine, *N*-Nitroso-, 79-0239
 Lung Neoplasms
 Carbon Dioxide, 79-0100
 Curium, 79-0363
 Einsteinium, 79-0370
 Mammary Neoplasms, Experimental
 Benzo(a)pyrene, 79-0289
 Dimethylamine, *N*-Nitroso-, 79-0289
 Nose Neoplasms
 Diethylamine, *N*-Nitroso-, 79-0198
 Pancreatic Neoplasms
 Ether, 2,4-Dichlorophenyl *p*-Nitrophenyl, 79-0229
 Prostatic Neoplasms
 Testosterone, 79-0338
 Thyroid Neoplasms
 Epidemiology, 79-0557

 Estrogenic Substances, Conjugated, 79-0534
 Estrogens, 79-0316, 79-0318
 Hypertension, 79-0318
 Obesity, 79-0318

Adenofibroma

- Mammary Neoplasms, Experimental
 - Benzo(a)pyrene, 79-0289
 - Dimethylamine, *N*-Nitroso-, 79-0289
- 4,4'-Stilbenediol, α,α' -Diethyl-
 - Height Control, 79-0314

Adenoma

- Colonic Neoplasms
 - Hydrazine, 1,2-Dimethyl-, 79-0163
- Liver Neoplasms
 - Contraceptives, Oral, 79-0029, 79-0309
- Lung Neoplasms
 - Carbamic Acid, Ethyl Ester, 79-0203, 79-0491
- Mammary Neoplasms, Experimental
 - Benzo(a)pyrene, 79-0289
 - Dimethylamine, *N*-Nitroso-, 79-0289
- Nitrous Acid, Sodium Salt
 - Aniline, *N*-Methyl-, 79-0049
 - Morpholine, 79-0049
 - Piperazine, 79-0049
- Pancreatic Neoplasms
 - Serine, Diazoacetate (Ester), 79-0183
- Parathyroid Neoplasms
 - Radiation, Ionizing, 79-0344
- Pituitary Neoplasms
 - Contraceptives, Oral, 79-0536
- Respiratory Tract Neoplasms
 - Diethylamine, *N*-Nitroso-, 79-0198
- Thyroid Neoplasms
 - Transplantation, Heterologous, 79-0349

Adenosine Cyclic 3',5' Monophosphate

- Asbestos
 - Colon, Rat, 79-0394
- 4,4'-Stilbenediol, α,α' -Diethyl-
 - Vagina, Neonatal Mouse, 79-0028
- Wood Fibers
 - Colon, Rat, 79-0394

Adenosine Triphosphatase

- Hepatoma
 - Barbituric Acid, 5-Ethyl-5-phenyl-, 79-0199
 - Diethylamine, *N*-Nitroso-, 79-0199
- Virus, Avian Myeloblastosis
 - Catalytic/Antigenic Properties, 79-0401
- Virus, Reo
 - Catalytic/Antigenic Properties, 79-0401
- Virus, Rous Sarcoma
 - Catalytic/Antigenic Properties, 79-0401

Adenosine Triphosphate

- Benz(a)anthracene-7-methanol, 12-Methyl-
 - Binding, Covalent, 79-0257

Adipose Tissue

- Breast Neoplasms
 - Carcinogen, Chemical, 79-0088
 - Epidemiology, 79-0088

Adrenal Glands

- Benz(a)anthracene, 7,12-Dimethyl-
 - Carcinogenic Potential, Hamster, Rat, 79-0182
 - Cell Division, 79-0182
- t*-Butylamine, *N*-Ethyl-*N*-nitroso-
 - Carcinogenic Potential, Hamster, Rat, 79-0182
 - Cell Division, 79-0182
- Butyric Acid, 2-Amino-4-(ethylthio)-
 - Carcinogenic Potential, Hamster, Rat, 79-0182
 - Cell Division, 79-0182

Adrenal Glands (cont'd)

- Diallylamine, *N*-Nitroso-
 - Carcinogenic Potential, Hamster, Rat, 79-0182
 - Cell Division, 79-0182
- Indole-3-acetic Acid, 1-(*p*-Chlorobenzoyl)-5-methoxy-2-methyl-
 - Carcinogenic Potential, Hamster, Rat, 79-0182
 - Cell Division, 79-0182
- Nitrous Acid, Sodium Salt
 - Carcinogenic Potential, Hamster, Rat, 79-0182
 - Cell Division, 79-0182
- s*-Triazine, Hexahydro-1,3,5-trinitroso-
 - Carcinogenic Potential, Hamster, Rat, 79-0182
 - Cell Division, 79-0182

Adriamycin

- HeLa Cells
 - DNA Replication, 79-0226

Aflatoxin B1

- Ames Test
 - Wheat Sprout Extract, 79-0169
- Ammonia
 - Food Contamination, 79-0156

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index is \$75.00, Domestic and \$90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

ORIGINAL ARTICLES

SYMPTOMS

SYMPTOMS		SYMPTOMS		SYMPTOMS	
1. Headache	2. Dizziness	3. Nausea	4. Vomiting	5. Diarrhea	6. Constipation
7. Stomach pain	8. Abdominal pain	9. Back pain	10. Joint pain	11. Muscle pain	12. Fatigue
13. Weakness	14. Irritability	15. Depression	16. Anxiety	17. Nervousness	18. Sleeplessness
19. Loss of appetite	20. Weight loss	21. Fever	22. Chills	23. Night sweats	24. Pale skin
25. Rapid pulse	26. High blood pressure	27. Low blood pressure	28. Rapid breathing	29. Slow breathing	30. Irregular breathing
31. Increased urination	32. Decreased urination	33. Frequent urination	34. Nocturnal urination	35. Urinary retention	36. Urinary incontinence
37. Urinary pain	38. Urinary odor	39. Urinary color	40. Urinary consistency	41. Urinary volume	42. Urinary pH
43. Urinary specific gravity	44. Urinary sediment	45. Urinary casts	46. Urinary crystals	47. Urinary mucus	48. Urinary blood
49. Urinary pus	50. Urinary leukocytes	51. Urinary erythrocytes	52. Urinary bacteria	53. Urinary fungi	54. Urinary parasites
55. Urinary viruses	56. Urinary toxins	57. Urinary enzymes	58. Urinary hormones	59. Urinary antibodies	60. Urinary antigens

These symptoms are common to many diseases and should be considered in the differential diagnosis of each case. The physician should take a careful history and perform a thorough physical examination to determine the cause of these symptoms. Laboratory tests, such as blood and urine analysis, may be helpful in identifying the underlying condition. Treatment should be directed at the cause of the symptoms rather than the symptoms themselves.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)

REVIEW

79-0601 Genetic and Related Effects of *Vinca rosea* Alkaloids. (Eng) Degraeve, N. (Laboratoire de Genetique, Universite de Liege, Rue Forgeur 15, B-4000 Liege, Belgium). *Mutat Res* 55(1): 31-42; 1978.

The antitumor properties, stathmokinetic effect, mutagenicity, and teratogenicity of the *Vinca rosea* alkaloids vinblastine (VLB) and vincristine (VCR), together with their effects on DNA and RNA synthesis, chromosomes, and gametogenesis, are reviewed. These compounds appear to be indoleindole dimers in which the indole is linked by a C-C bond to the aromatic ring of the dihydroindole. VLB is used to treat some lymphosarcomas, choriocarcinomas, monocytic leukemias, and Hodgkin's disease, VCR to treat lymphosarcomas, Hodgkin's disease, and acute lymphoblastic leukemias in children. At the cellular level, VLB and VCR produce effects similar to those of colchicine: accumulation of mitotic figures, arrested metaphases with highly coiled chromosomes, multipolar anaphases with lagging chromosomes in the interpolar region, tendency to polyploidy by doubling of the chromosomes but failure of chromatid separation, and, at high concentrations, pyknosis. The alkaloids can bind with nucleic acids, but the bonds disappear at high ionic strength, indicating that they are weakly electrostatic. In cell cultures, both alkaloids inhibit RNA synthesis. VLB interferes with some metabolic reactions related to DNA synthesis. The alkaloids cause chromosome damage in root tips, hamster cell lines, and human lymphocytes. After treatment of mice *in vivo*, VLB and VCR gave a positive response in the micronucleus test. Under specific conditions, it seems that *Vinca* alkaloids can interfere with spermatogenesis. All experiments attempting to demonstrate a mutagenic activity of the two alkaloids yielded negative results. In the hamster, VLB and VCR had a dose-dependent embryocidal effect when injected *iv* on the eighth day of gestation. At doses similar to those used in therapy, there was evidence of gross malformations (microphthalmia, anophthalmia, exencephaly, spina bifida). (81 refs)

79-0602 Describing the Validity of Carcinogen Screening Tests. (Eng) Cooper, J. A. (Div. Cancer Cause and Prevention, NCI, Bethesda, MD, 20014); Saracci, R.; Cole, P. *Br J Cancer* 39(1): 87-89; 1979.

Concepts related to the development and validation of carcinogen screening tests are reviewed. The validity of a screening test is described by its sensitivity (the proportion of carcinogens that give a positive result) and specificity (the proportion of non-carcinogens that give a negative result). The predictive value (PV) of a test (the proportion of carcinogens among the substances that test positive) reflects the sensitivity and specificity of the test and the prevalence (propor-

tion) of carcinogens among the tested substances. As the prevalence changes so does the PV of a program; and the dependence of PV on the specificity becomes stronger as the prevalence declines. Two additional items of information are necessary for the meaningful interpretation of the sensitivity and specificity of a test: the identity of the substances used to evaluate the test and the criterion of a positive test outcome. (8 refs)

79-0603 Butorphanol: A Review of Its Pharmacological Properties and Therapeutic Efficacy. (Eng) Heel, R. C. (Australasian Drug Information Services, P.O. Box 34-030, Auckland 10, New Zealand); Brogden, R. N.; Speight, T.M.; Avery, G. S. *Drugs* 16(6): 473-505; 1978.

The pharmacological properties and therapeutic efficacy of butorphanol (BTP), a synthetic analgesic that is a narcotic agonist and antagonist, are reviewed. In rats given 1 or 2 mg/kg/day BTP *po* for 78 wk, no neoplasms occurred that were not observed with a similar frequency in controls. (67 refs)

79-0604 Genetic Activities of Hycanthone and Some Other Antischistosomal Drugs. (Eng) Ong, T. M. (Natl. Inst. Occupational Safety and Health, ALOSH, Morgantown, WV, 26505). *Mutat Res* 55(1): 43-70; 1978.

The genetic activities of some antischistosomal drugs, particularly hycanthone, are reviewed. Recent studies have shown that hycanthone is a potent mutagen in *Salmonella* and mammalian cells in culture, and that it is mutagenic in several mammalian and submammalian test systems. However, it failed to induce mutations in the mouse specific locus test system. Hycanthone is teratogenic in mice and rabbits. It induces transformation in Rauscher murine leukemia virus-infected mammalian cells and increases the incidence of tumors in schistosome-infected mice and hamsters. The mechanism of mutagenesis and other biological activities probably involves covalent binding of this compound to DNA as well as intercalation between DNA bases. Studies of structure-activity relationships have shown that the mutagenicity of antischistosomal agents can be disassociated from their antischistosomal activity. Lucanthone, niridazole, furapromidium, metrifonate, and oxamniquine have also been shown to be mutagenic in *Salmonella* and/or other test systems. However, data on the mutagenicity and other genetically related activities of these compounds are limited. With the available data for hycanthone, it is difficult to extrapolate its potential mutagenic, teratogenic, and carcinogenic hazard to humans. (138 refs)

- 79-0605 Rotenone: A Possible Environmental Carcinogen (Letter to Editor)?** (Eng) Gosalvez, M. (Bioquímica Experimental, Clínica Puerta Hierro, Universidad Autónoma, Madrid, Spain); Diaz-Gil, J. J. *Eur J Cancer* 14(12): 1403-1404; 1978.

Rotenone, a compound that induces mammary fibroadenomas in albino rats at very low po doses, is widely used in the US and several other countries as an insecticide, pesticide, and piscicide. Ingestion of rotenone by humans through food and drinking water contaminated with this compound may be substantial. Therefore, rotenone should be considered an environmental carcinogen. (9 refs)

- 79-0606 Cytotoxic Effects of Maleic Hydrazide.** (Eng) Swietlinska, Z. (Inst. Biochemistry and Biophysics, Polish Acad. Sciences, 02-532 Warsaw, Rakowiecka 36, Poland); Zuk, J. *Mutat Res* 55(1): 15-30; 1978.

The cytotoxicity of maleic hydrazide (MH), a herbicide and suppressor of plant growth, is reviewed. MH inhibits the synthesis of nucleic acids and proteins in plants and in animal tumor cells. Mutagenicity studies in various systems yielded contradictory results. MH has potent chromosome-breaking activity in plant cells but weak activity in animal cells. MH was carcinogenic to mice and rats in two studies. Plants can break down MH into several products, one of which, hydrazine, is a well-known mutagen and carcinogen. (120 refs)

- 79-0607 Mutagenicity, Carcinogenicity and Teratogenicity of Procarbazine.** (Eng) Lee, I. P. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Dixon, R. L. *Mutat Res* 55(1): 1-14; 1978.

The mutagenic, carcinogenic, and teratogenic effects of procarbazine (N-isopropyl- α -(methylhydrazino)-p-toluamide: MIH) are reviewed. Experimental and clinical studies strongly suggest that MIH can induce point-mutation chromosomal damage, mutagenicity, antifertility effects, carcinogenicity, and teratogenicity. The molecular mechanism by which it may produce these effects has not been completely elucidated. However, DNA and RNA have been shown to be alkylated at various positions of the nucleotides following exposure to MIH and/or its metabolites. This process has been hypothesized to be a mechanism of mutagenic, carcinogenic, and teratogenic action. Genetic counseling is necessary in any patient exposed to chemotherapeutic agents with mutagenic potential. The antifertility effects of MIH may be reversible or irreversible, depending upon both the dose and duration of chemotherapy, especially in treating Hodgkin's disease. Risks from teratogenic effects of MIH in humans are very small and can easily be circumvented. MIH has been shown to be carcinogenic in experimental animals, but whether this is the case in humans is uncertain. However, reports of secondary

tumors arising in cancer patients during or after chemotherapy are becoming available. Cancer patients receiving combination chemotherapy that includes MIH should be informed of the possible genetic and carcinogenic risks. (99 refs)

- 79-0608 Genetic Material and Cancer: Chemical Carcinogenesis.** (Fre) Zajdela, F. (No affiliation given); Sarasin, A.; Tambourin, P. *Lyon Med* 240(16): 273-280; 1978.

Mechanisms of chemical carcinogenesis are reviewed and related to physical, genetic, and viral carcinogenesis. Theories of DNA repair are explained with the use of illustrative diagrams. (no refs)

- 79-0609 Tumor Promoters: Effects on Proliferation and Differentiation of Cells in Culture.** (Eng) Diamond, L. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); O'Brien, T. G.; Rovera, G. *Life Sci* 23(20): 1979-1988; 1978.

The effects of phorbol diester tumor promoters on the proliferation and differentiation of cells in culture are reviewed, and the relation of these effects to the mechanism of tumor promotion is discussed. Exposures of cells to a phorbol tumor promoter may produce some or all of the following effects: increased prostaglandin, polyamine, RNA, and late DNA synthesis; increased phospholipid metabolism; increased plasminogen activator production; decreased early DNA synthesis; decreased thymidine uptake; decreased expression of large-external-transformation-sensitive (LETS) protein; and altered membrane glycoproteins. Tumor promoters inhibit terminal differentiation of cells in culture, which agrees with in vivo observation that tumor promoters alter normal cell differentiation. Tumor promoters may act by stimulating cell cycling and preventing withdrawal from the cycle into a differentiating pathway. A transient block in differentiation that favors proliferation of the stem cell population could lead to proliferation and amplification of a cell population in which the potential for malignancy had been initiated by a carcinogen but not yet expressed. It is also possible that inhibition of differentiation may be only a secondary result of a more basic effect of tumor promoters on cells that is directly related to their promoting activity. (78 refs)

- 79-0610 The Interaction of Nitrites with Food, Drugs, and Contaminants.** (Eng) Greenland, S. (Div. Epidemiology, Sch. Public Health, Univ. California, Los Angeles, CA, 90024). *J Environ Health* 41(3): 141-143; 1978.

Several thousand compounds occurring in water, food, and medications are capable of reacting with nitrites to produce N-nitroso compounds, a high percentage of which have been

found to be potent carcinogens. Proper controls on food and water levels of nitrites and on the additives and contaminants that react with nitrites must be developed. (34 refs)

79-0611 Carcinogenicity of Benzo(a)pyrene Derivatives: The Bay Region Theory. (Eng) Jerina, D. M. (Natl. Inst. Arthritis, Metabolism and Digestive Diseases, NIH, Bethesda, MD, 20014); Thakker, D. R.; Yagi, H.; Levin, W.; Wood, A. W.; Conney, A. H. *Pure Appl Chem* 50(9/10): 1033-1044; 1978.

Carcinogenicity data for benzo(a)pyrene (BP), benz(a)anthracene (BA), and numerous known and potential metabolites of these polycyclic hydrocarbons (HC's) are reviewed in light of the bay region theory of HC-induced carcinogenicity. The foundation of this theory rests on initial observations of remarkably high chemical reactivity for the epoxide ring in BP diol epoxides. According to the theory, diol epoxides on angular benzo rings of polycyclic HC's, in which the epoxide ring forms part of a "bay region" of the HC, are prime candidates for ultimate carcinogens. The tumor data firmly establish that the 7,8-dihydrodiol of BP and the 3,4-dihydrodiol of BA are proximate carcinogens and that the 7,8-diol 9,10-epoxides and the 3,4-diol 1,2-epoxides are ultimate carcinogens derived metabolically from the respective HC's, and they support the bay region theory. Perturbational molecular orbital calculations indicate that the electronic properties of the π -electron system are responsible for the unusually high chemical reactivity of the diol epoxides. (52 refs)

79-0612 Trends and Reliability of Data on Environmental Cancer. (Eng) Albrecht, R. M. (Bureau Radiological Health, Food and Drug Admin., Rockville, MD, 20857). *J Air Pollut Control Assoc* 29(1): 54-56; 1979.

The reliability of data concerning environmental cancer is considered in relation to presumably authoritative statements regarding environmental causes of cancer. Statistics on cancer incidence may have great deficiencies, especially when comparing (1) developed with underdeveloped countries and (2) incidence and mortality data in developed countries 15-20 yr ago with current data. When two or more agents interact, it is difficult to ascertain and quantify the effect of each; it may not be realistic to attribute a certain cancer to only one agent. There is no realistic common definition of environmental agents, making it difficult to have a common understanding of the quantitative relationship between environmental agents and specific cancers. The estimate that 80%-90% of cancers are environmental and can be prevented is not reliable. It has also been claimed that exogenous and environmental stimuli cause 30%-40% of human cancers. These stimuli include smoking, alcohol, and sunbathing, which should be considered personal habits rather than environmental agents. Several investigators have argued that the lowest reported cancer rates represent baseline or natural rates and that any

surplus is due to environmental agents. The argument would be more persuasive if hard data only were being dealt with. (11 refs)

79-0613 Harmful Effects of Cadmium. (Swe) Elinder, C. G. (Omgivningshygieniska avdelningen, Statens naturvårdsverk, Stockholm, Sweden); Friberg, L.; Piscator, M. *Lakartidningen* 75(47): 4365-4368; 1978.

The environmental and toxicological aspects of cadmium are reviewed. Recent studies show an increased risk of prostate cancer and, possibly, of lung cancer among workers exposed occupationally to certain forms of cadmium. Local sarcomas were found in animals following repeated sc or intratesticular injections of cadmium. (31 refs)

79-0614 Symposium: Awkward Medicolegal Problems in Asbestos-induced Disease. Risk Factors in Asbestosis Exposure. (Eng) Elmes, P. C. (MRC Pneumoconiosis Unit, Llandough Hosp., Penarth, Glamorgan CF6 1XW, Wales). *J R Soc Med* 71(12): 914-916; 1978.

The medicolegal aspects of disease entities resulting from asbestos exposure are discussed from the standpoint of level of exposure. Asbestosis as a cause of serious disabling disease and premature death following high exposure is uncommon now. However, a worker with partial disablement due to asbestosis who is a heavy smoker is at very high (70%-100%) risk of developing lung cancer. A moderate level of asbestos exposure (2-15 fibers/cm³) over a 50-yr working life results in some radiologically identifiable airway changes in most individuals, but the patient's age and smoking habits make the amount of airway disability due to asbestosis debatable. In this individual, the real danger again is from cancer of the lung. The risk of lung cancer in nonsmokers with this occupational history is increased approx fourfold. A heavy smoker has increased his lung cancer risk 10-20 times. Mesothelioma is not of medicolegal importance at moderate exposure levels, as when there is a history of occupational exposure, all cases are 100% attributable. At low continuous or occasional high exposures, lung cancer is probably not a significant risk. Mesothelioma presents the primary medicolegal problem, because it may arise with no accompanying asbestosis or pleural plaques, and occupational exposure may be long since forgotten. (4 refs)

79-0615 Exposure to Asbestos and Its Harmful Effects. A Brief Review. (Nor) Melbostad, E. (Lungeavdelingen, Rikshospitalet, Stockholm, Norway). *Tidsskr Nor Laegeforen* 98(31): 1563-1564; 1978.

Studies on asbestos exposure and the effects of inhaled asbestos are reviewed. Workers handling and processing asbestos

are the most exposed, people living in the vicinity of asbestos mines and of factories where asbestos is used are also exposed. The harmful effects of exposure depend on its intensity and duration and on the type of the fibers; short fibers, such as those of amphibole, are the most hazardous. In terms of harmful effects, short-term intense exposure is equivalent to long-term low-level exposure. Asbestos causes pleural plaques, diffuse interstitial lung fibrosis, lung cancer, and pleural and peritoneal mesotheliomas. The latent period is 3-30 yr, and usually 20-40 yr for mesothelioma. The incidence of lung cancer among workers with asbestosis was 15% in 1947 and rose to over 50% in 1963. Asbestos exposure alone increases the lung cancer risk about fourfold, but exposure with smoking increases the risk by a factor of 92. Although 80%-90% of all mesothelioma patients have been exposed to asbestos, only about 5% of all asbestos-exposed workers develop mesothelioma. The mesothelioma incidence appears to be highest after exposure to crocidolite. There is no relationship between asbestos-induced mesothelioma and smoking. (no refs)

- 79-0616** **Implanted Polymers.** (Eng) Bagnall, R. (ICI Pharmaceuticals Div., Hurdsfield Industrial Estate, Macclesfield, Cheshire SK10 2NA, England). *Chem Br* 14(12): 598-602; 1978.

Physical properties appear to play a major role in determining the biocompatibility of implanted polymers. Implant shape (sharp corners or edges), rigidity, and surface roughness can all induce excess collagen synthesis, and small particles caused by wear may produce a reaction similar to the fibrogenic response to inorganic dusts. Large, nonporous implants have induced tumors in rodents at the implant site after 6 mo, an effect called solid state or foreign body carcinogenesis. These tumors have not been reported in humans, in spite of the use of large implants such as mammary prostheses. (17 refs)

- 79-0617** **Skin Cancer.** (Spa) Galvan Aguilera, A. S. (Fundacion para el Diagnostico Temprano del Cancer, A. C. Av. Oaxaca 96-202, Mexico 7, D.F., Mexico). *Patol Quir Citol Esfoliativa* 4(4): 145-153; 1978.

The epidemiological, clinical, histopathological, prophylactic, and therapeutic aspects of skin cancer are reviewed. Skin cancer affects slightly more men than women, mainly at advanced age. It is more frequent in white than in dark-skinned or black races; the incidence is highest among whites living in tropical areas, such as Australia and New Zealand. The mortality per 100,000 was 7.1 in Australia, 6.7 in New Zealand, 4.6 in Switzerland, 4.5 in Denmark, 4.0 in Czechoslovakia and the USA, 3.4 in France, 1.5 in Mexico, 1.3 in Japan, 0.6 in El Salvador, 0.5 in Panama, 0.3 in Honduras, and 0.1 in Thailand in 1972-1973. The most common types of skin cancer are basal-cell carcinoma, epidermoid car-

cinoma and malignant melanoma. The epidemiological data show a clear correlation between skin-cancer mortality and intense exposure to UV radiation. (11 refs)

- 79-0618** **Photoreactivation in Mammalian Cells.** (Eng) Sutherland, B. M. (Biology Dept., Brookhaven Natl. Lab., Upton, NY, 11973). *Int Rev Cytol Suppl* 8: 301-334; 1978.

Cellular photoreactivation (PR) phenomena and the properties and function of photoreactivating enzymes (PRE's) are reviewed, along with the role of PR in the repair of UV damage in humans. PRE deficiencies (0%-50% of normal level) have been found in xeroderma pigmentosum (XP) cells, and true defects in PRE's are reflected by a lower rate of PR in XP cells with similar backgrounds of other repair processes. Investigations revealed that some XP patients were normal in excision repair but had defects in other repair processes. Others seemed to be deficient in excision and postreplication repair, PR, and in an enzyme nicking the phosphodiester backbone at depurination sites. In PR and in excision, defects can be detected in individuals normal with respect to sun sensitivity or solar carcinogenesis (CG). A simplified scheme for explaining these apparent contradictions is a proposal for summing the cell's total repair capacity. In this scheme, excision and postreplication repair and PR are weighted equally. In spite of several drawbacks, the scheme has two appealing features: all repair parameters are measurable and can be compared to clinical manifestations of solar CG, a good correlation between repair defects and CG is apparently provided. Concerning the origin of repair defects, there does not seem to be a general defect in messenger RNA or protein synthesis leading to abnormalities of many proteins. The possibility of coordinate control of repair processes is attractive and may explain the existence of multiple repair defects. Several lines of evidence indicate that repair enzyme levels are regulated in cells. There does not seem to be a correlation in the number of repair defects in cells with multiple repair defects. (84 refs)

- 79-0619** **Symposium on Photochemotherapy (PUVA). Possible Long-Term Hazards of Photochemotherapy with Psoralens and Near Ultraviolet Light.** (Eng) Bridges, B. A. (MRC Cell Mutation Unit, Univ. Sussex, Falmer, Brighton BN1 9QG, England). *Clin Exp Dermatol* 3(4): 349-353; 1978.

The advisability of using photochemotherapy with psoralens and near UV (A) radiation (PUVA) is weighed against its cytotoxic and genotoxic hazards. According to current criteria, PUVA must be regarded as an established skin carcinogen in mice. In humans, the only published evidence for carcinogenicity comes from experience with four xeroderma pigmentosum patients, who showed an accelerated rate of

appearance of skin tumors within 1 mo of starting treatment with trimethylpsoralen. (21 refs)

- 79-0620 Postirradiation Neoplasia: A Symposium.** (Eng) Scanlon, F. (Dept. Surgery, Evanston Hosp., Evanston, IL); Berk, R. S.; Khandekar, J. D. *In: Curr Probl Cancer* 3(6): 45 pp.; 1978.

The literature concerning radiation carcinogenesis, specifically, the development of thyroid, bone marrow, skin, parathyroid gland, salivary gland, breast, lung, head and neck, pelvic, and pediatric tumors plus Hodgkin's disease and sarcomas, is reviewed. A large amount of evidence suggests that radiation given in infancy and childhood is etiologically related to subsequent development of carcinoma in the head and neck. Apparently, very high doses of radiation are less likely to be carcinogenic than lesser amounts. Very small doses are probably not carcinogenic either. In general, the younger the patient at the time of irradiation, the greater the risk of subsequent development of carcinoma. However, the breast seems to be an exception, as it is more sensitive to radiation-induced carcinogenesis between the ages of 10 and 35. Chronic low doses of radiation seem to be particularly carcinogenic in humans. The latent interval between irradiation and the appearance of carcinoma in most sites averages about 30 yr. Leukemia, however, usually appears 5-8 yr after irradiation. Irradiation for malignant tumors in all parts of the body probably predisposes to the later development of irradiation carcinoma in long-term survivors. Radiation-treated patients should be followed carefully for life. (151 refs)

- 79-0621 Non-A and Non-B Viral Hepatitis.** (Ita) Rossolini, A. (Istituto di Clinica delle Malattie Infettive, Università Siena, Siena, Italy); Almi, P.; Cellesi, C.; Figura, N. *Recent Prog Med (Roma)* 64(4): 391-403; 1978.

Studies of hepatitis induced by herpes simplex virus (HSV), cytomegalovirus (CMV), and Epstein-Barr virus (EBV) are reviewed. Compared with the incidence of HSV infections, HSV-induced hepatitis is rare, affecting mainly undernourished subjects, patients with severe infectious diseases, and patients with immunodeficiency. The incidence of CMV-induced hepatitis has shown a recent increase due to the widespread use of blood transfusion and immunosuppressive therapy. Infectious mononucleosis associated with EBV-induced hepatitis can be due to oral transmission or, in an increasing number of cases, to blood transfusion. (41 refs)

- 79-0622 Virus and Human Cancers.** (Fre) Van Tieghem, N. (Laboratoire de Microbiologie et d'Immunologie, Faculté de Médecine de Bruxelles, Brussels, Belgium). *Brux Med* 58(10): 551-561; 1978.

Experimental and theoretical evidence for the relationship of viruses to human cancer is reviewed. Criteria for oncogenicity, and the biological, biochemical, morphological, and immunological properties of DNA and RNA viruses responsible for animal and human tumors are outlined. (no refs)

- 79-0623 Leukemia and Lymphoma: Infrequent Manifestations of Common Viral Infections? A Review.**

(Eng) Francis, D. P. (Hepatitis Lab. Div., Center Disease Control, 4402 N. 7th St., Phoenix, AR, 85014); Essex, M. *J Infect Dis* 138(6): 916-923; 1978.

The clinical, virologic, and epidemiologic aspects of feline leukemia virus (FeLV) are reviewed with emphasis on factors that are most applicable to the search for cancer-causing viruses in humans. After an incubation period of 2-4 wk, FeLV causes a relatively mild infection; a small number of infected cats (44/100,000) develop leukemia or lymphoma months or years after the initial infection. Most cats exposed to FeLV produce both neutralizing antibodies and feline oncornavirus membrane-associated antigen (FOCMA) antibodies and suffer no complications. Animals that do not produce antibodies develop a persistent viremia and often tumors. Thus, failure to detect antibodies to suspected virus-induced antigens in humans with cancer is not surprising. Neither is the failure to detect virus, viral particles, viral structural antigens, or viral genetic sequences, since oncogenic viruses can infect a host and induce a malignancy without producing infectious virus. The identification of cancer-causing viruses is also complicated by the requirement for other factors in addition to the etiologic agent for tumor induction, eg, immunosuppression, age at infection, and genetic background. Emphasis should be placed on establishing a link between human lymphoreticular cancer and retroviruses and/or DNA viruses. (32 refs)

- 79-0624 From Experimental Animal Models to Human Lymphoid Tissue Neoplasia: Search for a Viral Etiology.** (Eng) Kaplan, H. S. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305). *In: Recent Results Cancer Res* 64: 325-336; 1978.

Experimental studies of laboratory mammals have offered many clues to the etiology and pathogenesis of human lymphomas and leukemias, including the observation that viruses are the universal etiologic agents of these neoplasms in all mammalian species studied to date, with ionizing radiation and chemical leukemogens serving to activate latent leukemogenic viruses rather than cause somatic mutation. The possibility of the existence of human leukemia-lymphoma viruses is very real, but in order to be conclusively proven as such, any suspect virus must successfully meet a stepwise series of criteria. Some of these steps are demonstrated by a C-type RNA virus isolated from a cell line (SU-DHL-1) established by culturing tumor cells from dif-

fuse histiocytic lymphoma patients. The virus contains 70S RNA, reverse transcriptase (RT) activity, and has an equilibrium density of approx 1.15 g/ml in sucrose gradients. It has the capacity to induce syncytia in rat XC cells and, electron microscopically, it resembles other mammalian C-type RNA viruses in size and morphology. Studies of the inhibition of its RT activity by antibodies to the RT's of other C-type RNA viruses suggest some degree of relatedness to subhuman primate viruses. The virus failed to propagate on various fibroblastic and other nonlymphoid indicator cell lines. However, the addition of filtered virus preparations to fresh human buffy coat mononuclear (or normal human spleen) cell cultures or to the adherent cells from these cultures (initially composed almost entirely of monocytes and later of macrophages) caused reproducible changes in the growth behavior and culture morphology of the infected normal human cells. Cells bearing aneuploid chromosome complements were observed in some of these cultures after 1-4 wk, similar to cultures of rhesus monkey buffy coat cells. Additional in vitro studies in progress should determine whether the virus has lymphoma-inducing potential for normal human cells of the corresponding cell type. Demonstration that the virus is human will require careful biochemical and seroepidemiologic studies. (58 refs)

79-0625 Recent Data on the Pathogenic Role of Epstein-Barr Virus (EBV). (Fre) Seigneurin, J. M. (Laboratoire de Virologie, C.H.U. de Grenoble, BP 217 X, F 38043 Grenoble Cedex, France); Lenoir, G. *Nouv Presse Med* 7(44): 4003-4004, 1978.

EBV has been demonstrated to be the cause of infectious mononucleosis, but its role in Burkitt's lymphoma and nasopharyngeal carcinoma has not yet been fully proved. There is an evident genetic predisposition toward nasopharyngeal carcinoma. (7 refs)

79-0626 Mechanisms and Abnormalities of Immune Regulation. (Eng) Russell, I. J. (Dept. Immunology, Mayo Medical Sch., Rochester, MN, 55901); Tomasi, T. B. *Pathobiol Annu* 8: 1-33; 1978.

Current concepts regarding the mechanisms that regulate antibody production are reviewed, and some exemplary diseases in which regulation may be abnormal are identified. Specific topics include (1) the interactions of macrophages and lymphocytes, cells involved in the humoral immune response; (2) soluble factors that modify immunoglobulin (Ig) synthesis or replace certain necessary cell-mediated functions; and (3) the relevance of the abnormality of these mechanisms to selected immune diseases. Until recently, most defects in immune-deficiency syndromes were explained on the basis of developmental defects in the B cells. However, certain immune disorders may be based on imbalances between regulatory cells; ie, helper, suppressor, and amplifier T cells, as well

as macrophages. It is the net or algebraic sum of the various regulatory positive and negative influences that determines the magnitude of the resulting immune response. In some diseases, however, the initiating event may secondarily lead to a regulator abnormality that subsequently perpetuates the disease. The characteristics of X-linked hypogammaglobulinemia, common variable immunodeficiency, the secondary hypogammaglobulinemia seen in multiple myeloma, rheumatoid arthritis, sarcoidosis, chronic active hepatitis, and systemic lupus erythematosus are described. Elaboration of soluble amplifiers and suppressors of Ig synthesis by normal mammalian cells requires exogenous stimulation by mitogens and certain antigens. In contrast, amplifier materials are produced spontaneously by cells from certain patients with certain autoimmune diseases. It may be that they are activated by an as yet unknown antigenic challenge, such as self-antigens modified by an extrinsic agent such as a virus. The molecular size and properties of soluble factors are outlined to stress both the similarities and heterogeneity of the products obtained from different systems. Factors found in disease states may represent normal mechanisms operating in an abnormal or uncontrolled manner. (122 refs)

79-0627 Problems in Defining the Nude Mouse. (Eng) Rygaard, J. (Pathological-anatomical Inst., Municipal Hosp., Copenhagen K, Denmark). *Folia Biol (Praha)* 24(5): 289-299; 1978.

Several discrepancies among nude mice are reviewed with respect to their influence on studies using these animals. For example, the amount of genetic material showing accordance between the background strain, heterozygous $nu/+$ or homozygous nu/nu , is not known; this is particularly important in reconstitution experiments or in mixed lymphocyte culture tests. Immunoglobulin (Ig) levels in nude mice, particularly IgG and IgA levels, are different in various laboratories due to the genetic background of the mice used and the milieu in which they live. Nude mice have been used for the heterotransplantation of a large number of human tumors, and the take rate is approx 35%. Although the successful transplants have garnered the most attention, the unsuccessful transplants raise several interesting questions concerning whether the tumors are thymus-dependent or -independent; the role of macrophages, natural killer cells; and specific antibodies; and the effect of cytostatic drugs or x-irradiation. Following transplantation into nude mice, tumors that metastasize and kill their human host usually adopt a benign behavior. A few transplanted human tumors will metastasize in nude mice; most will not. In spite of these and other discrepancies and unanswered questions, many questions have also been resolved with the use of the nude mouse, such as the diversity of B cells, the nature of B-cell mitogens, and the specificity and role of T cells in immunology. (43 refs)

79-0628 Lymphomagenesis and Autoimmunization Caused by Reactions of T-Lymphocytes to Incompatible Structures of the Major Histocompatibility Com-

plex: A Concept of Pathogenesis. (Eng) Gleichmann, E. (Dept. Immunohistopathology, Central Lab. Netherlands Red Cross Blood Transfusion Service, Univ. Amsterdam, P.O. Box 9190, Amsterdam, Netherlands); Melief, C. J.; Gleichmann, H. *In: Recent Results Cancer Res* 64: 292-315; 1978.

Since T-cell anti-major histocompatibility complex (MHC) reactions comparable to those seen during the graft-vs-host reaction (GVHR) may also occur in an autologous system, it has been postulated that they may lead to the same diseases as in the semiallogeneic parent- F_1 hybrid system. This hypothesis is reexamined in light of recent findings. In F_1 hybrids undergoing chronic GVHR, autoantibody formation is triggered by the abnormal assistance provided to normally present but inactive autoreactive B cells of the F_1 recipient by donor T cells reacting to their incompatible H-2 structures (allogeneic effect). A related immunologic mechanism (back-stimulation) may be responsible for the proliferation of H-2-incompatible F_1 B cells in the presence of donor T cells. Persistent proliferation, mainly of F_1 B cells, leads to immunoblastic sarcomas in GVH F_1 mice. It is not known whether GVH-induced lymphomas develop independently of C-type RNA viruses or whether lymphoid tissues stimulated by chronic GVHR provide a favored microenvironment for viruses of otherwise low oncogenicity. GVH lymphomagenesis may also be caused by C-type RNA viruses for which an assay has not been developed. However, two lines of evidence support the above hypothesis: (1) results obtained with animal GVH models, in which immunoblastic sarcoma, angiogenesis, and autoantibody formation were induced by reactions of parental T lymphocytes toward genetically incompatible MHC structures; (2) recent discoveries pointing to similarity in T-cell reactions toward genetically foreign MHC structures on the one hand and self-MHC structures on cells rendered foreign by chemicals or infectious agents on the other. This concept implies that small numbers of T lymphocytes are crucial for the pathogenesis of certain lymphomas that, according to current nomenclature and thinking, are thought to be exclusively disorders of B lymphocytes. (168 refs)

79-0629 The Contribution of Electron Microscopy to the Diagnosis of Tumors. (Eng) Mackay, B. (Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Osborne, B. M. *Pathobiol Annu* 8: 359-405; 1978.

The value of electron microscopy (EM) in tumor diagnosis is demonstrated by a review of cases studied at the M. D. Anderson Hospital in Houston, Texas. The cases discussed are grouped under three broad headings, carcinomas, small round cell tumors, and sarcomas. Carcinomas illustrate both the practical value of EM in solving diagnostic problems and its limitations. EM can lead to a specific diagnosis or it may offer no information that cannot be obtained from light microscopy (LM). However, most cases fall somewhere in between, and EM studies may narrow a differential diagnosis

or provide reassurance by confirming a LM impression. Small round cell tumors are often difficult to identify by LM because of their morphologic similarity. This is an area in which EM can offer a significant contribution in almost every case. Problems in identifying sarcomas are often encountered at the LM level, and EM studies can lead to enhanced precision in diagnosis and subclassification. However, the clinical significance of the contribution may be less than that in the other two groups with regard to prediction of biologic behavior and influence on selection of therapy. Despite its variable contribution, EM can be helpful in most problem cases if good material is available for study and when findings are correlated with the light microscopic histology and the available clinical information. (174 refs)

79-0630 Cell Cycle. General Aspects. (Spa) Galanti, N. (Unidad de Biología Celular, Universidad de Chile, Santiago de Chile, Chile). *Rev Med Chil* 105(12): 927-933; 1977.

Studies on the cell cycle are reviewed with special regard to hyperplasia. The cell cycle is regarded as a biological system in which the control mechanisms that ensure the orderly performance of cell growth, differentiation, and organ maintenance exert their effects. Thus, in the cell cycle the cells may go from one mitosis to the next, or leave the proliferative cycle in G_1 or R_2 , from the resting states (G_0 or R_1), the cells may return to the proliferative cycle, or undergo irreversible differentiation. Considering these possibilities, hyperplasia may be due to 1) a shortening of the proliferative cycle; 2) a shift of cells from the resting state to the cycle; 3) a decrease in cell loss, and/or 4) the influx of cells from populations other than the original. Experiments have shown that the cell cycle time in normal tissues and tumor tissues (Ehrlich ascites tumor; C3H breast tumor; bronchial, gastric, and endometrial carcinoma; acute myelogenous leukemia; HeLa cells and glioma cells) is practically of the same order of magnitude. Thus, hyperplasia results from the recruitment of resting cells and/or from a decrease in the rate of cell loss, rather than from a shortening of the proliferative cycle. In keeping with this finding, recent investigations tend to concentrate on the mechanisms responsible for the G_0 to G_1 transition and on the processes of cell aging and death, rather than on the factors responsible for changing the length of the cell cycle. (34 refs)

79-0631 On the Terms "Reticulosis" and "Reticulum Cell Sarcoma" with Regard to the Modern Concept of the Monocyte Macrophage System. (Eng) Leder, L. D. (Institutes für Pathologie, Westdeutsches Tumorzentrum, Universität Essen, Hufelandstrasse 55, D-4300 Essen 1, W. Germany). *Klin Wochenschr* 56(22): 1091-1096; 1978.

The monocyte macrophage system has replaced the concept of the reticuloendothelial system, and it is not independent

of but is closely related to the myeloid system. All reticulososes have been found to belong to the myeloid or lymphatic system, and most reticulum cell sarcomas or malignant histiocytic lymphomas seem to be of lymphatic rather than macrophage origin, representing high-grade malignant lymphomas, possibly immunoblastic sarcomas. Thus, the use of reticulosis and reticulum cell sarcoma is meaningless and confusing, since the concepts upon which these terms are based are no longer tenable. (42 refs)

79-0632 Surface Morphology of Lymphoreticular Cells: Review of Data Obtained from Scanning Electron Microscopy. (Eng) Polliack, A. (Dept. Hematology, Hadassah Univ. Hosp., Hadassah Medical Sch., Jerusalem, Israel). In: *Recent Results Cancer Res* 64: 66-93; 1978.

Scanning electron microscope (SEM) studies of the surface morphology of normal and malignant lymphocytes and other WBC are reviewed. Normal lymphocytes can be distinguished from monocytes and macrophages on the basis of their surface architecture. Lymphocytes have fingerlike microvilli and generally lack ruffles, but monocytes and macrophages lack multiple microvilli and have broad-based ruffles. Although B and T lymphocytes have a different surface morphology, as proved by other modes of microscopy and cryofracture, they should not be distinguished solely on the basis of number of microvilli seen under the SEM. Circulating leukemic lymphocytes and Sezary cells show a spectrum of surface morphology with varying numbers of microvilli. Leukemic lymphoblasts may also occasionally show microvilli, but more frequently they lack them or display only a small number. Ruffles are rarely encountered in all these leukemic cell types. Plasma/myeloma cells have surface blebs and microvilli, but hairy cells are readily distinguished from chronic lymphocytic leukemia cells by the presence of ruffles and clusters of microvilli. In some cases of histiocytic lymphoma, cells have well-developed ruffled membranes resembling those seen on monocytes and monoblasts, but in other cases cells are lymphoid and display multiple microvilli. In most cases, myelo/mono/myelomonocytic cells are readily distinguished from lymphocytic cells on the basis of surface architecture and are characterized by raised ridgelike profiles and/or prominent ruffled membranes. SEM is a useful adjunct to other modes of microscopy, and it may contribute to the diagnosis of lymphoreticular and leukemic disorders. (106 refs)

79-0633 Cell Surface Structures, Differentiation and Malignancy in the Haemopoietic System. (Eng) Greaves, M. (Membrane Immunology Lab., Imperial Cancer Res. Fund, Lincoln's Inn Fields, London, England). In: *Symp Soc Exp Biol* 32: 429-442; 1978.

Studies of the role of cell-surface events in hematopoietic differentiation and maturation using human leukemic cells are

reviewed. Most of the acute nonmyeloid leukemias that appear lymphoid or "undifferentiated" do not appear to express specific gene products of T and B lymphocytes (T-cell antigens and immunoglobulin, respectively) on their surface. Therefore, acute lymphoblastic leukemia (ALL) cells are likely frozen at an earlier pre-T, pre-B stage of development. Studies of chronic myeloid leukemia (CML) have suggested that (1) CML can frequently involve transformation of a pluripotent stem cell; (2) since Philadelphia chromosome (Ph⁺)-positive and Ph⁺-negative leukemias can have similar or identical phenotypes, the phenotype components (eg, membrane antigens) are reflections of normal gene activity; ie, they are precursor or stem cell markers; (3) CML can be used as a monoclonal system to map normal cellular relationships and developmental sequences in hematopoiesis (HP). The ALL and Ia-like antigens are believed to be normal gene products of the target stem cells for acute leukemia transformation, and they may play an important role in early HP. It is hypothesized that malignancy and regeneration involve selective proliferation of stem cells that are more common in fetuses and children than in adults and that the antigenic properties of these cells are effectively normal; ie, ALL and Ia-like antigens are normal stem cell antigens. It is suggested that ALL⁺ cells are not myeloid progenitors and that IA is expressed on at least some stem cells committed to the granulocytic-macrophage pathway. Clinical evidence suggests that T cells can regulate hemopoietic development (of granulocytic and erythroid lineages). Regulatory cell interactions controlled by the major histocompatibility gene locus may have a central significance in HP and may not be restricted to mature immunocompetent cells. (64 refs)

79-0634 A History of the Reed-Sternberg Cell. (Eng) Taylor, C. R. (Section Immunopathology, Los Angeles County/USC Medical Center, 2025 Zonal Ave., Los Angeles, CA, 90033). *Biomedicine* 28(4): 196-203; 1978.

The evidence of a possibly histocytic or lymphocytic origin of the Reed-Sternberg cell is reviewed, along with implications of a lymphocytic origin. The concepts presented indicate that the different histological forms of lymphoma (including Hodgkin's disease) are not indicative of a different cellular origin, but merely reflect (1) the radical morphological and functional changes expressed by a single progenitor cell, the lymphocyte, during its proliferation cycle and (2) the overall kinetics of the neoplastic lymphocyte population. (85 refs)

79-0635 Monitoring Disease in England and Wales: Methods Applicable to Routine Data-Collecting Systems. (Eng) Fraser, P. (London Sch. Hygiene and Tropical Medicine, Keppel St., London WC1E 7HT, England); Beral, V.; Chilvers, C. *J Epidemiol Commun Health* 32(4): 294-302; 1978.

Routine data-collecting systems and methods for disease surveillance in England and Wales are reviewed. Population-based correlation studies are being made to try to explain

disease trends by relating routine health statistics to possible causative agents on a secular, geographical, or occupational basis. In addition, information collected by routine general-purpose systems is being linked as a means of identifying and following individuals exposed to potential hazards. (49 refs)

- 79-0636 Cancer of the Colon and Rectum.** (Swe) Holmstrom, B. (Kirurgiska kliniken, Serafimerlasaret, S-112 83 Stockholm, Sweden). *Lakartidningen* 75(46): 4266-4268; 1978.

The etiological, epidemiological, clinical, and therapeutic aspects of cancer of the colon and rectum are described. A high correlation was found between cancer of the colon and rectum and high fecal bile acids and Clostridia content. Cancers of the colon and rectum account for 7.8% and 4.8% of all malignant tumors, respectively, in men, and for 8.3% and 3.6%, respectively, in women. (5 refs)

- 79-0637 Early Diagnosis of Cancer.** (Spa) Schulz Contreras, M. (Patologia de la Facultad de Medicina, U.N.A.M., Mexico); Castillo Nava, J.; Cervantes, L.; Gaitan Galarza, V.; Paredes Aguilera, R.; del Rio Huidobro, J. *Patol Quir Citol Esfoliativa* 4(1): 3-26; 1978.

Studies of carcinogenic agents, cancer epidemiology, and the early diagnosis of cancer are reviewed. The overall cancer mortality appears to be significantly higher in Northern European countries (Scotland, Luxembourg, England, Wales, and Finland) than in tropical countries (294-332/100,000 vs 40-137/100,000). A positive correlation was found between the gastric cancer incidence and the consumption of smoked meat and fish, and a negative correlation was found between the consumption of a diet rich in wheat products and antioxidant-containing preservatives. A positive correlation was found between low-roughage diet and cancer of the colon, because low-roughage food passes through the bowels more slowly than does food rich in fibers so that the intestinal mucosa is exposed to carcinogens for a prolonged period. The low incidence of cancer of the penis in circumcised men and of cervical cancer in their spouses is believed to be linked not only with the absence of the carcinogenic smegma factor but also with higher hygienic standards. (no refs)

- 79-0638 Pineal Gland, F.S.H., and Breast-Cancer Aetiology (Letter to Editor).** (Eng) Adami, H. O. (Dept. Surgery, Univ. Hosp., S-750 14 Uppsala, Sweden); Rimsten, A.; Wide, L. *Lancet* 2(8103): 1312-1313; 1978.

Data contradicting a role for the pineal gland in the etiology of breast cancer are presented. An androgenic rather than an estrogenic predominance was found in one study of postmenopausal (pm) women with breast cancer, and in another, serum follicle-stimulating hormone (FSH) values did not differ in the patient and control groups. In addition, the pm ovary loses its capacity to respond to FSH by estrogen secre-

tion, and pm estrogen production is accounted for almost exclusively by peripheral metabolism of the androgenic precursors, mainly derived from the adrenals. (5 refs)

- 79-0639 Thyroid Disease in Relation to Breast Cancer.** (Eng) Vorherr, H. (Dept. Obstetrics-Gynecology, Univ. New Mexico, Sch. Medicine, 915 Stanford Dr. N. E., Albuquerque, NM, 87131). *Klin Wochenschr* 56(23): 1139-1145; 1978.

The relationship of thyroid disease to human breast cancer is reviewed. There have been suggestions that hypothyroidism may protect women from breast cancer and, conversely, that it may be associated with an increased risk of breast cancer. It has been hypothesized that a deficiency in circulating thyroid hormones hypersensitizes the mammary glandular epithelium toward prolactin and estrogens, thereby aiding in the development of breast neoplasia. Although there is some data indicating that thyroid hormone replacement therapy increases the risk of breast cancer, this has been contested and the American Thyroid Association recommends that hypothyroid patients should take replacement medication if indicated. The metabolic effects of thyroid hormone in hyperthyroid conditions have been described as protecting against breast cancer, but the possibility of a thyroid hormone-induced increase in estrogen activity, with an enhanced risk of breast cancer, also seems to exist. Thus, the role of thyroid hormone in the development and/or growth of breast cancer remains undefined. The controversy can be satisfactorily resolved only by a prospective study, preferably of postmenopausal women, correlating thyroid, pituitary, and adrenocortical function with estrogen status and the results of periodic breast and genital examinations. (67 refs)

- 79-0640 Epidemiology of Breast Cancer.** (Eng) Saracci, R. (Unit Epidemiology and Biostatistics, International Agency Res. Cancer, 150 Cours Albert-Thomas, 69008, Lyon, France); Repetto, F. In: *Semin Oncol* 5(4): 342-350; 1978.

Epidemiological data on breast cancer (BC) are reviewed. After skin cancer, BC is the most frequent cancer in women of Western countries. High rates are found in Northern and Western Europe and North America, low rates in Africa, Latin America, and Asia, and intermediate rates in Eastern and Southern Europe. The age-incidence curve in Western countries shows two peaks, one at approx age 45 and another much later, indicative of both a premenopausal (related to ovarian activity) and a postmenopausal (accounting for approx two-thirds of cases) type of BC. Approx 10%-15% of BC's show familial aggregation, particularly the premenopausal, bilateral type. No firm association has been detected between BC and various genetic markers, but of current interest are markers specifically related to possible steps in the pathogenesis of BC. Theories largely involve the hormone composition of women, and several observations indicate that BC risk is directly related to duration of menstrual life, with its cyclic elevations of hormone (particularly estro-

gens) levels. In this regard, the estriol (E_3) ratio hypothesis appears to explain many well-documented features of BC. However, no pattern of hormone production or hormone milieu has been firmly established in relation to BC risk. Environmental factors, such as ionizing radiation, long-term use of reserpine, intake of high-fat diet, and presence of an apparently B-type RNA virus in human milk, have all been implicated in BC development to varying degrees. In brief, the current emphasis is on multicausality, including genetic, hormonal, nutritional, viral, and other environmental elements, as the key to understanding BC etiology. (19 refs)

- 79-0641** **Circumcision in the Prophylaxis of Cancer of the Penis and Uterine Cervix.** (Por) Tractenberg, M. (No affiliation given); Gindin, L. R. *Psicanalis da Circuncisao* 111-137; 1977.

Literature on the significance of circumcision in the prevention of cancer of the penis and uterine cervix is reviewed. Even though the smegma seems to contain carcinogenic components, the prophylactic value of circumcision does not appear clearly from the literature. Most authors believe that adequate hygiene of the genitals in both sexes is a more effective prophylactic measure than circumcision. Consequently, routine prophylactic circumcision is unjustified and inhumane due to its ineffectiveness and possible intraoperative and postoperative complications. (31 refs)

- 79-0642** **The Management of Tumors of the Upper Cervical Spine.** (Eng) Dunn, E. J. (Fallon Clinic, Inc., 630 Plantation St., Worcester, MA, 01505); Anas, P. P. *Orthop Clin North Am* 9(4): 1065-1080; 1978.

The management of benign and malignant tumors of the atlas and axis is discussed. Of the 28 atlantoaxial tumors reported in the literature, two-thirds were metastatic, the most common primaries being lung, breast, prostate, and thyroid cancers, myeloma and lymphoma. Primary atlantoaxial tumors included chordoma, osteochondroma, giant cell tumors, osteoid osteoma, aneurysmal bone cysts, and osteogenic sarcoma. Vigorous therapeutic measures should be aimed at completely ameliorating pain, reversing neurologic impairment, and attaining cervical stability. The transpharyngeal needle biopsy of Ottolenghi is a safe and dependable method for obtaining tissue for diagnosis from the anterior elements of C1 and C2. Cervical myelography is necessary to distinguish between the two basic mechanisms that are responsible for cord compression. Flexion and extension views, cineradiography, angiography, and tomography may further assist in patient evaluation. Anterior surgery in this region should be reserved for patients with benign tumors or cancer patients with a good prognosis and specific indications. Tracheostomy should be performed to avoid postoperative complications after anterior surgery. Most patients with metastatic disease are not surgical candidates, but many are helped by radiation therapy, chemotherapy, and a soft cervical collar or other

conservative external immobilization devices. Bone grafting should be used when possible to establish cervical fusion. Methyl methacrylate, alone or in combination with a bone graft, can be used to avoid problems associated with grafting in patients with metastatic disease. It also allows early postoperative ambulation without the need for cumbersome external immobilization devices. (27 refs)

- 79-0643** **Neoplastic Complications of Neurofibromatosis.** (Eng) Pantoja, E. (Dept. Radiology, USAF Medical Center, Wright-Patterson AFB, OH, 45433); Llobet, R. E.; Taveras, J. E. *Cutis* 22(6): 677-680; 1978.

Neurofibromatosis associated with secondary neoplasms is discussed. Some of the tumors that occur in neurofibromatosis are histologically benign; the most common being gliomas and meningiomas of the CNS. Other tumors of neurogenic derivation found in this condition include neurosarcoma, pheochromocytoma, and medullary carcinoma of the thyroid. The association between neurofibromatosis and cutaneous malignancies, carcinoma of the colon, leukemia, Wilms' tumor, and cancer of the kidney is of doubtful significance. Neurosarcomas are generally considered to represent a malignant degeneration of neurofibromatous tissue. The earliest sign of sarcomatous degeneration is usually a sudden and rapid increase in the size of an old, previously quiescent neurofibroma. In doubtful cases, the diagnosis may be established by biopsy of a cutaneous lesion. The treatment of choice is either wide local excision or amputation, depending on the location and extent of the lesion. These tumors are highly radioresistant and the prognosis of peripheral neurosarcoma associated with neurofibromatosis is very poor unless the tumors are completely removed. Benign CNS tumors may be curable if amenable to complete resection. (15 refs)

- 79-0644** **X-Ray Findings in the Skull in Neurofibromatosis.** (Ger) Galanski, M. (Radiologisches Klinik d. WWU, 4400 Munster, W. Germany); Benz, G. *ROEFO* 129(6): 757-761; 1978.

The x-ray findings in the skull in neurofibromatosis are reviewed, and x-rays of briefly described cases are included. Several types of tumors (neurinoma, neurofibroma, meningioma, craniopharyngioma, and chiasma tumors) are associated with this disease. The differential diagnosis depends on detection of mesodermal dysplasia, changes secondary to blastomatous processes, macrocephalus, and intracranial calcifications. (40 refs)

- 79-0645** **Multiple Endocrine Neoplasia, Type 2b.** (Eng) Carney, J. A. (Dept. Surgical Pathology, Mayo

Clinic and Mayo Foundation, Rochester, MN, 55901); Sizemore, G. W.; Hayles, A. B. *Pathobiol Annu* 8: 105-153; 1978.

The historical development, inheritance, diagnosis, pathology, prognosis, and treatment of multiple endocrine neoplasia, type 2b (MEN 2b) are reviewed. Age and sex factors are discussed, and pathologic changes in various parts of the body are presented. The syndrome is characterized by medullary thyroid carcinoma (MTC), pheochromocytoma (PC), ganglioneuromatosis, and a variety of skeletal and connective tissue abnormalities. Total thyroidectomy is necessary once abnormal basal or stimulated plasma immunoreactive calcitonin concentrations have been demonstrated. Although the PC's are rarely malignant, they are potentially lethal because of their cardiovascular effects. Since adrenal involvement is usually bilateral, total bilateral adrenalectomy with excision of any extraadrenal paraganglioma is the surgical treatment. Parathyroid hyperplasia occurs rarely in the syndrome; its treatment should be limited to excision of enlarged parathyroid glands. Both sympathetic and parasympathetic nerves and ganglia exhibit hypertrophy, hyperplasia, and structural disorders, a group of changes designated ganglioneuromatosis. This may be largely responsible for the striking eye and oral findings (diffuse lip enlargement and apparent eversion of the eyelids) and also for some of the serious symptoms and complications of the syndrome, particularly those referable to the alimentary tract. Ganglioneuromatosis is also found in the salivary glands, pancreas, gallbladder, upper respiratory tract, and urinary bladder. Increased growth of long bones, ribs, and skull results in a marfanoid habitus; skeletal and joint abnormalities and increased laxity of ligaments are also present. Ninety cases of MEN 2b have been reported, and although follow-up information is incomplete, 27 patients are known to have died as a result of the syndrome. The direct causes of death were MTC (15 deaths), PC (10 deaths), and alimentary tract complications (2 deaths). An additional 21 patients have metastatic MTC. Patients having the appearance characteristic of MEN 2b should be evaluated for thyroïdal C-cell and adrenal medullary function. (90 refs)

79-0646 Adenoid Cystic Carcinoma (Cylindroma) in the Head and Neck. A Clinical Review of 82 Cases.

(Eng) Zielke-Temme, B. (Dept. Radiology, Universitätsklinik Munster, Munster, W. Germany); Wannenmacher, M. *Acta Radiol [Oncol]* (Stockh) 17(5): 407-413; 1978.

Clinical data on 82 patients (52 women, 30 men) treated between 1958 and 1976 for adenoid cystic carcinoma (ACC) of the head and neck are reviewed. ACC is a rare malignant tumor that grows slowly, and local recurrence and generalized disease may occur even after long symptom-free periods. Approx half of the 82 tumors were located in the intraoral mucous or minor salivary glands, mostly in the hard and soft palate. The age of the patients ranged from 15 to 81 yr (mean 55.4 yr), with 68% being in the fifth and sixth decades. Mean duration prior to treatment was 1.7 yr. (35 refs)

79-0647 The Comparative Epidemiology of Selected Neoplasms Between Dogs, Cats, and Humans.

A Review. (Eng) Hayes, H. M. (Environmental Epidemiology Branch, NCI, 3C07 Landow Building, Bethesda, MD, 20014). *Eur J Cancer* 14(12): 1299-1308; 1978.

The epidemiologic features of tumors at nine different sites in dogs and cats are reviewed and compared with those of the corresponding human tumors whenever possible. Testicular neoplasms are the leading cause of cancer death in US men 25-29 yr old and the second in hospital prevalence in the dog. The primary difference between these tumors in men and dogs concern the incidence of certain cell types. The pathogenesis of spontaneous ovarian tumors in women and animals is obscure, but the similarity of the disease in women and dogs appears to make the latter a suitable model for testing suspected ovarian carcinogens. The ratio of female to male dogs with mammary gland tumors is about the same as the ratio in humans, and the distribution of the cancer by age in bitch dogs appears similar to that in women. There is also marked similarity in the epidemiological features of cancer of the kidney, urinary bladder, thyroid gland, chemoreceptor system (the glomus jugulare, glomus pulmonale, aortic body, and carotid body), brain, and blood-lymphatic system in humans and dogs. There is little information on cancer in cats, but what is available also shows a marked similarity to that on human cancers. (100 refs)

79-0648 Epidemiology of Malignant Tumors in Occupational Groups: Methods and Peculiarities of Study.

(Eng) Smulevich, V. B. (Oncological Scientific Center, USSR Acad. Medical Sciences, Kashirskoye shosse 6, 115478 Moscow, USSR); Bulbulian, M. A.; Katsnelson, B. A. *J Occup Med* 21(1): 11-14; 1979.

Research methods and problems encountered in epidemiological studies of occupational cancer are reviewed. In order to define certain malignant tumors as occupational, it is necessary to prove by epidemiological methods that a given form of cancer is observed in workers in specific industries significantly more often than in control groups. The relatively small size of industrial groups makes it necessary to use various methodological devices to obtain valid data, such as calculation of morbidity and death rate indices on data obtained for a number of years and relating them to the total size of the contingent studied during the same period; calculation of data by person-year methods; and calculation of data by person-years under risk. Difficulties in studying the epidemiology of occupational cancer include the long latent period, changes of occupation, frequent absence of archival materials for the period studied, and absence of environmental data. The development of a tumor of a certain site at a younger age than in the control group and the leveling out of characteristic sex differences in tumor prevalence are epidemiological criteria of occupational carcinogenesis. (16 refs)

79-0649 Geographical Variation in Cancer Incidence: A Clue to Causation. (Eng) Doll, R. (Dept. Regius Professor Medicine, Univ. Oxford, Oxford, England). *World J Surg* 2(5): 595-602; 1978.

The geographical variation in the incidence of 16 different cancers is discussed with special reference to esophageal cancer. Areas of high and low incidence of each of these cancers are tabulated. Differences in diet may be one of the etiological factors underlying these variations. (28 refs)

79-0650 The New Peptide Hormones of the Gut and Their Clinical Significance. (Eng) Bloom, S. R. (Dept. Medicine, Histochemistry, Royal Postgraduate Medical Sch. Hammersmith Hosp., DuCane Road, London W12 OHS, England); Polak, J. M. *Acta Gastroenterol Belg* 41(7/8): 371-393; 1978.

The gut endocrine system and the new peptide hormones of the gut are discussed in relation to their clinical significance.

Eight peptide hormones have their major biological actions through the circulation: gastrin is released from the stomach; pancreatic polypeptide is released from the pancreas; cholecystokinin, secretin, motilin, and gastrin inhibitory peptide are released from the upper small intestine; and neurotensin and enteroglucagon are released from the lower small intestine. These hormones are released in a characteristic way after a meal and the pattern is altered in a diagnostic manner by alimentary disease. The best recognized gut hormone disease occurs as a result of endocrine tumors. Hormonal peptides may be released only locally from an endocrine cell or they may be produced by and released from a neuron to have a brief local action. It has been proposed that the endocrine system is an out-pouching of the brain. The occurrence of several hormonal peptides (vasoactive intestinal peptide, somatostatin, substance P, enkephalin, bombesin, neurotensin, and gastrin/cholecystokinin) in both the gut and brain - where they may act as neurotransmitters - supports this concept. A better understanding of alimentary control systems should allow better insight into the etiology of human gut diseases. (13 refs)

CHEMICAL CARCINOGENESIS

79-0651 Mutagenic Analysis as a Means of Detecting Carcinogens in Foods. (Eng) Commoner, B. (Center Biology Natural Systems, Washington Univ., Box 1126, St. Louis, MO, 63130); Vithayathil, A.; Dolara, P. *J Food Protection* 41(12): 996-1003; 1978.

The possible origin of the mutagens that occur in commercial beef extract and in commercial foods containing beef extract was investigated. These mutagens were first identified in the nutrients used to culture the *Salmonella* for the Ames bacterial mutagenicity assay, and they require activation by the microsomal mixed-function oxidase system. The mutagens were not found in uncooked beef tissue or in beef stock. However, they were formed when beef stock was boiled extensively to produce beef extract. The same mutagens (as evidenced by their chromatographic behavior) were found when ground beef hamburgers were cooked at temperatures > 150-200 C. Well-done hamburgers cooked on an electric frying pan or hot plate or in an electric hamburger cooker (cooking temperatures 190-300 C) contained the mutagens. Hamburgers cooked under the heating element of an electric broiler or in a microwave oven (but not on the "browning tray") contained no significant mutagenic activity. Mutagen content increased with cooking time and was concentrated in the outer surface of the cooked hamburgers. These results show that mutagens found in beef extract and in cooked hamburgers represent a possible risk of unknown magnitude to persons ingesting them. However, the nutritional benefits of hamburgers can be enjoyed without incurring this risk, by a suitable choice of cooking methods. (15 refs)

79-0652 Monitoring and Risk Assessment by Means of Alkyl Groups in Hemoglobin in Persons Occupationally Exposed to Ethylene Oxide. (Eng) Calleman, C. J. (Dept. Radiology, Wallenberg Lab., Univ. Stockholm, S-106 91 Stockholm, Sweden); Ehrenberg, L.; Jansson, B.; Osterman-Golkar, S.; Segerback, D.; Svensson, K.; Wachtmeister, C. A. *J Environ Pathol Toxicol* 2(2): 427-442; 1978.

The degree of alkylation of histidine residues in Hb from blood samples collected from employees of sterilization plants using ethylene oxide (EtO) was determined. The max daily level of exposure was estimated to be 75 to 380 ppm/hr, depending on working site within the factory. Quantitative determination of N-3-(2-hydroxyethyl)histidine by mass fragmentography and ion-exchange amino acid analysis gave consistent results. Chronic exposure for > 18 wk (the lifetime of 1 RBC) would result in a steady-state degree of Hb alkylation nine times the weekly increment in the degree of alkylation. There was an acceptable agreement between the genetic risk estimate per unit dose and the one expected from mouse

data, the value for the EtO being approx 10 mrad-equivalents (ppm/hr)⁻¹. Because of its low mol wt, solubility in water and lipids, and rapid distribution to all parts of the body, it is likely that EtO induces a spectrum of cancers similar to that observed following whole-body exposure to penetrating low-linear energy transfer (low-LET) radiation. Although the finding of a cluster of two leukemia cases in one sterilization plant was statistically significant, it was not proof of the carcinogenicity of EtO. The dose of EtO corresponding to the limit of occupational risk to low-LET radiation would be 10 ppm/hr/wk, corresponding to an av concentration of 0.25 ppm. (35 refs)

79-0653 Multifocal Epithelioma in a Case of Psoriasis Treated with an Arsenical. (Pol) Frezer, O. (Klinika Dermatologii, Instytut Chorob Ulkadu Nerwowego i Narzadow Zmyslow AM, ul. Przybyszewskiego 49, 60-355 Poznan, Poland). *Przegl Dermatol* 65(6): 683-685; 1978.

A 70-yr-old man treated for 4 yr with potassium arsenite soln for psoriasis developed a multifocal basal cell epithelioma 12 yr after treatment. (8 refs)

79-0654 A Simple Method of Arsenic Speciation. (Eng) Brown, E. J. (Inst. Marine Science, Univ. Alaska, Fairbanks, AK, 99701); Button, D. K. *Bull Environ Contam Toxicol* 21(1/2): 37-42; 1979.

Low concentrations of As(V) can easily and routinely be separated from As(III) in water, soil, sediment, and biological samples using procedures similar to those for phosphate detection. The procedures are based on the fact that arsenate forms on alcohol-extractable molybdate complex but arsenite does not. Once separated, total As(III) or As(V) can then be determined by atomic absorption or distillation, allowing As speciation at part-per-billion levels. (15 refs)

79-0655 X-Ray Microanalysis of Asbestos in Tissue Culture Cells (Meeting Abstract). (Eng) Kindig, O. R. (Dept. Cell Biology, Tokyo Medical Dental Univ., Tokyo, Japan); Mizuhira, V. *J Electron Microsc (Tokyo)* 27(4): 379; 1978. (no refs)

79-0656 Cyclic Nucleotide Concentrations in Asbestos-induced Peritoneal Mesotheliomas in Rats (Meeting Abstract). (Eng) Stevens, R. H. (Radiation Res.

Lab., Univ. Iowa, Iowa City, IA, 52242); Will, L. A.; Osborne, J. W.; Cole, D. A.; Donham, K. J. *Cell Tissue Kinet* 11(6): 689; 1978. (no refs)

- 79-0657 Asbestos Cement Dust Inhalation by Hamsters.** (Eng) Wehner, A. P. (Dept. Biology and Energy Systems, Battelle, Pacific Northwest Lab., Richland, WA, 99352); Dagle, G. E.; Cannon, W. C.; Buschbom, R. L. *Environ Res* 17(3): 367-389; 1978.

The biological effects of inhaled asbestos cement (AC) dust were determined in male Syrian golden hamsters exposed to AC aerosols (average fiber count, 5-120 fibers/cm³) at concentrations of about 1-10 µg/liter for 3 hr/day, 5 days/wk. AC treatment had no consistent or significant effects on body or lung wt or survival time. The only histologic changes related to AC dust exposure were in the lungs. Ferruginous bodies associated with alveolar macrophages were found distributed throughout the lung and occasionally aggregated in areas around respiratory bronchioles. The number of ferruginous bodies and macrophages in the exposed animals increased with aerosol concentration and exposure time. The incidence of ferruginous bodies did not decrease in animals that were withdrawn from AC dust exposure prior to sacrifice. The incidence of slight fibrosis increased with dose in animals treated with AC dust for 15 mo before sacrifice. No other lesions were clearly related to AC dust exposure, and there were no primary respiratory carcinomas or mesotheliomas. (20 refs)

- 79-0658 Directed Health Survey of Workers Exposed to Asbestos.** (Swe) Hedenberg, L. (Goteborgs stads forvaltningshalsovard, Anders Perssonsgaten 2, S-416 64 Goteborg, Sweden); Hermansson, L.; Liden, M. A.; Thiringer, G. *Lakartidningen* 78(45): 4151-4152; 1978.

A total of 197 men (aged 17-66 yr, av 45 yr) with occupational exposure to asbestos (mainly machine operators, repairmen, pipe-layers, and pipefitters) were subjected to chest x-ray and pulmonary function tests. Pleural plaques were detected as the only change in 41 workers, 24 of whom were smokers. All 41 had normal lung function tests. Asbestosis (pulmonary fibrosis and pleural plaques) were found in 8 workers: 4 of them (1 nonsmoker and 3 smokers) exhibited restrictive ventilatory impairment, while the 4 others (all smokers) had normal lung function. The chest x-ray was normal in 146 cases, x-ray changes due to unrelated causes were found in 2; 72 of these 148 men were smokers. No one under the age of 51 had pulmonary fibrosis, and no one under the age of 38 had pleural plaques. (no refs)

- 79-0659 Cytology of the Respiratory Tract in Asbestos Miners.** (Eng) Plamenac, P. (Inst. Pathology,

Medical Faculty, Univ. Sarajevo, Sarajevo, Yugoslavia); Nikulin, A.; Pikula, B.; Markovic, Z. *Acta Med Jugosl* 32(4): 297-309; 1978.

The sputum specimens of two groups of asbestos miners, 23 cigarette smokers and 16 nonsmokers, were analyzed cytologically. The age of the miners ranged from 21 to 41 yr (av 27), the length of their occupational exposure from 1 to 17 yr (av 8). All the miners had normal chest roentgenograms and showed no signs of acute or chronic respiratory or other organic disease. All specimens contained a considerable amount of polymorphonuclear WBC, and all showed abnormal columnar cell findings. Squamous metaplasia was present in 19 smokers (10 without atypia, 9 with atypia) and in 9 of the nonsmokers (5 without atypia, 4 with atypia). None of the samples contained asbestos or ferruginous bodies. Several of the smokers and nonsmokers had eosinophilia (9 and 5, respectively), siderophages (21 and 12), and respiratory mucus spirals (19 and 5). The difference between the two groups in the incidence of mucus spirals was the only one that was statistically significant. It is concluded that long-term asbestos exposure can produce extensive alterations in the bronchial epithelium. (40 refs)

- 79-0660 Asbestos Bodies in Sputum (Letter to Editor).** (Eng) Whitaker, D. (Hosp. & Univ. Pathology Services, Queen Elizabeth II Medical Centre, Nedlands, Western Australia, Australia). *Acta Cytol (Baltimore)* 22(6): 443-444; 1978.

The finding of asbestos bodies (AB) in the sputum as opposed to lung tissue is probably an indication of significant exposure and may identify a group at high risk of the development of pathologic lesions of the lung and/or pleura. Among 70 patients with AB in the sputum, 47 had lung lesions (12 malignant mesotheliomas, 4 lung cancers with asbestosis, 15 lung cancers without asbestosis, and 16 cases of asbestosis). The lesions were due to occupational exposure in 40 patients, 31 of whom worked in asbestos mines. (6 refs)

- 79-0661 Awkward Medicolegal Problems in Asbestos Workers.** (Eng) Robertson, A. J. (Royal Liverpool Hosp., Liverpool L7 8XN, England). *J R Soc Med* 71(12): 864; 1978.

Medicolegal problems concerning compensation cases for asbestos workers are summarized briefly. Adequate and thorough occupational histories (in view of the minimum 10- and 20-yr latent time for asbestosis and mesotheliomas respectively), and evidence of exposure to asbestos must be presented. Persons residing with asbestos workers are also subject to asbestos-related diseases. (6 refs)

79-0662 Analysis of Genome Integrity During Exposure of Cultured Mammalian Cells to Cadmium Chloride (Meeting Abstract). (Eng) Hildebrand, C. E. (Cellular and Molecular Biology Group, Los Alamos Scientific Lab., Univ. California, Los Alamos, NM, 87545); Walters, R. A. *Biophys J* 25(2, part 2): 229a; 1979. (no refs)

79-0665 Determination of Chromium in Working Areas by Atomic Absorption Spectrophotometry. (Rum) Dumitru, R. (Institutul de Igiena si sanatate publica, Bucharest, Romania); Ivanescu, A. *Rev Ig (Ig)* 27(3): 281-284; 1978.

An atomic absorption spectrophotometric method for determining chromium in the air of work areas, for example, in electroplating shops, is described. Chromium is sampled on membrane filters. The sensitivity of the method is 0.04 µg/ml. (21 refs)

79-0666 Direct-acting Mutagens in Automobile Exhaust. (Eng) Wang, Y. Y. (Sch. Public Health, Univ. California, Berkeley, CA, 94720); Rappaport, S. M.; Sawyer, R. F.; Talcott, R. E.; Wei, E. T. *Cancer Lett* 5(1): 39-47; 1978.

Samples of airborne particulates collected from Buffalo, New York, in 1961-1963 were assayed for mutagenicity to *Salmonella typhimurium* strains TA98, TA100, and TA1537, with and without rat liver microsome activation. The particulates were mutagenic to all three strains and did not require activation. Direct-acting (D-A) mutagenicity in TA98 was significantly correlated to the lead content of the sample, suggesting that automobile emissions might be the primary source of D-A airborne mutagens. Exhaust samples from passenger cars and from an experimental single-cylinder gasoline engine were also D-A mutagens in TA98, TA100, and TA1537; dose-response relationships were observed up to 1 mg/plate. Several fuels (iso-octane, premium leaded gasoline, regular low-lead gasoline, diesel fuel, and JP-4) and unused motor oil were not mutagenic, but used motor oil contained D-A mutagens. These results indicate that vehicular emis-

sions may contain D-A mutagens that result from combustion. The strain specificity and the fact that the mutagens were D-A rules out unsubstituted polycyclic aromatic hydrocarbons (PAH), aromatic amines, alkyl nitrosamines, or aliphatic epoxides, peroxides and hydroperoxides. Nitro-substituted PAH, some of which are direct-acting mutagens in *S. typhimurium*, may be the compounds observed in this study. Preliminary results with 6-nitrobenzo(a)pyrene support this suggestion. (29 refs)

79-0667 Ultrastructural Findings in Nasal Mucosa of Nickel Workers (Meeting Abstract). (Eng) Reith, A. (Norsk Hydro's Inst. Cancer Res., Oslo, Norway); Boysen, M.; Torjussen, W.; Solberg, L. A. *Ann Clin Lab Sci* 8(6): 503; 1978. (no refs)

79-0668 Induction of Renal Cancers by Intrarenal Injection of Nickel Subsulfide in Rats (Meeting Abstract). (Eng) Sunderman, F. W. (Univ. Connecticut Sch. Medicine, Farmington, CT); Maenza, R. M.; Hopfer, S. M.; Mitchell, J. M.; Allpass, P. R.; Damjanov, I. *Ann Clin Lab Sci* 8(6): 502; 1978. (1 ref)

79-0669 Morphological Transformation of Syrian Hamster Fetal Cells Induced by Nickel Compounds (Meeting Abstract). (Eng) Costa, M. (Inst. Materials Science, Univ. Connecticut, Storrs, CT, 06268); Nye, J.; Sunderman, F. W. *Ann Clin Lab Sci* 8(6): 502; 1978. (no refs)

79-0670 Serum Ceruloplasmin Concentrations in Rats with Primary and Transplanted Sarcomas Induced by Nickel Subsulfide. (Eng) Sunderman, F. W. (Dept. Lab. Medicine, Univ. Connecticut Sch. Medicine, P.O. Box G, Farmington, CT, 06032); Trudeau, E. A.; Horak, E.; Mitchell, J. M.; Allpass, P. R. *Ann Clin Lab Sci* 9(1): 60-67; 1979.

To study the value of serum ceruloplasmin (CPN) as an indicator of tumor progression, serum CPN concentrations were measured by p-phenylenediamine oxidase assay in sera from 30 control male Fischer rats, 5 rats with primary sarcomas induced by im injections of nickel subsulfide (Ni₃S₂), and 12 rats that had received Ni₃S₂-induced sarcoma transplants (sc) up to 6 wk earlier. The av serum CPN concentration in control rats was 0.35 g/liter, a value not significantly different from that in rats with primary sarcomas (0.38 g/liter). However, the max CPN concentration in rats that had received tumor implants 31 to 34 days earlier was 1.6-fold higher than the concentration obtained before tumor transplant. The CPN concentration was increased only 1.03-fold 32 days after sc injection of the NaCl vehicle alone. The av

latent period until death and av tumor diameter at death were greater in rats given sc transplants (5.7 wk from time of transplant and 8.1 cm, respectively) than in rats with primary sarcomas (16.4 wk from appearance of palpable tumor and 5.7 cm, respectively). The development of hyperceruloplasminemia in rats with transplanted sarcomas but not in rats with primary sarcomas was attributed to the greatly enhanced growth rates of the transplanted neoplasms. (63 refs)

- 79-0671 Carcinoma of the Cervix after Treatment with Prednisone and Azathioprine for Chronic Active Hepatitis.** (Eng) Norfleet, R. G. (Dept. Gastroenterology, Marshfield Medical Center, 1000 N. Oak Ave., Marshfield, WI, 54449); Sampson, C. E. *Am J Gastroenterol* 70(4): 383-384; 1978.

The case of a 24-yr-old woman who developed carcinoma of the cervix, in situ, after receiving immunosuppressive therapy for chronic active hepatitis is presented. The patient had received a total dose of 1,000 g of azathioprine and of 250 g of prednisone during a 5.5-yr period. The possibility that these drugs caused the malignancy is discussed, and evidence that hepatitis may be associated with increased cervical cancer incidence is reviewed. (9 refs)

- 79-0672 Risks in Chromium and Nickel Exposure for Stainless Steel Welders (Meeting Abstract).** (Eng) Stern, R. M. (Danish Welding Inst., Glostrup, Denmark). *Ann Clin Lab Sci* 8(6): 501; 1978. (no refs)

- 79-0673 Test of O,O-Dimethyl-1-hydroxy-2,2,2-trichloroethylphosphonate (Trichlorfon) for Carcinogenic Activity in Syrian Golden Hamsters (*Mesocricetus auratus* Waterhouse) by Intraperitoneal Administration.** (Ger) Teichmann, B. (Zentralinstitut für Krebsforschung, Akademie der Wissenschaften der DDR, Lindenberger Weg 80, DDR-1115 Berlin-Buch, E. Germany); Schmidt, A. *Arch Geschwulstforsch* 48(8): 718-721; 1978.

O,O-Dimethyl-1-hydroxy-2,2,2-trichloroethylphosphonate (TCP: Trichlorfon) was tested for carcinogenic activity following ip injection (20 mg/kg/wk) in male and female Syrian hamsters. The animals were treated for 90 wk, at which time the max total dose was 204 mg in the males and 206 mg in the females. The animals were observed for approx 10 more weeks, and animals that did not die spontaneously were killed at 100 wk after the beginning of treatment. The treated animals showed no significant difference in tumor incidence compared with controls, and this was true whether or not the animals were divided by sex. (7 refs)

- 79-0674 Sister Chromatid Exchange Frequencies in Cultured Human Cells Exposed to an Organophosphorus Insecticide: Dichlorvos.** (Eng) Nicholas, A. H. (Div. Human Genetics, Dept. Human Biology, Univ. Leuven, Minderbroedersstraat 12, B-3000 Leuven, Belgium); Vienne, M.; Van Den Berghe, H. *Toxicol Lett* 2(5): 271-275; 1978.

The frequency of sister chromatid exchanges (SCE's) was examined in human cells grown in the presence of bromodeoxyuridine and exposed for 72 hr to 2.5, 5, or 10 µg/ml dichlorvos (DDVP). In human lymphocytes, there was a dose-dependent decrease in SCE frequencies with increasing DDVP concentrations. Because there was evidence that dimethyl sulfoxide, used as a solvent for DDVP, might be responsible for these results, an experiment in which no solvent was used was carried out. Again, a decrease in SCE frequency with increasing DDVP concentration was apparent, although this decrease was not statistically significant. In human fetal fibroblasts, however, there was an increase in the number of SCE's with increasing DDVP concentration. Although the differences in the response of fibroblasts and lymphocytes to DDVP were statistically significant ($0.05 > p > 0.01$), they were insufficient to be of biological significance. (15 refs)

- 79-0675 A Technique for the Measurement of Breakage and Repair of DNA Alkylated In Vivo.** (Eng) Eastman, A. (Dept. Biochemistry, Univ. Vermont Coll. Medicine, Burlington, VT, 05405); Bresnick, E. *Chem Biol Interact* 23(3): 369-377; 1978.

To assess the level of DNA damage induced in the livers and lungs of A/J and C57BL/6J mice after administration of the alkylating agent methylmethanesulfonate (MMS), the squash alkaline elution technique has been modified. At 4 hr after ip administration of MMS (120 mg/kg), damage to DNA (labeled in a series of 7 sc injections of 25 µCi (³H)thymidine (50 Ci/mM) that produced a specific activity of approx 500 disintegrations/min/µg liver or lung DNA) was readily demonstrable. This damage was repaired in the liver by 24 hr. The lung, particularly in the A/J mice, exhibited an increased alkaline elution rate when compared with C57BL/6J mice, and repair was not entirely complete by 24 hr based on the rate of alkaline elution of DNA. The rate of elution was dependent upon temperature: as the temperature was varied from 15 to 25 C, the initial elution rate (% DNA/hr) went from 1.50 to 6.90 in lung, and from 0.25 to 2.13 in liver. It is hoped that this modification will have much utility in the investigation of DNA repair in vivo. (18 refs)

- 79-0676 Reactions of Bisulfite, an Environmental Chemical, with Nucleic Acids and Other Biological Substances.** (Eng) Hayatsu, H. (Faculty Pharmaceutical Sciences, Univ. Tokyo, Bunkyo-ku, Tokyo 113, Japan). *Pure Appl Chem* 50(9/10): 1063-1068; 1978.

Bisulfite (BS) + semicarbazide, hydrazine, hydroxylamine, or methoxyamine inactivated and induced mutations in bacteriophage λ , and the action of BS + each amine was synergistic. These phenomena are probably due to chemical modifications of phage DNA. The rapid inactivation of phage by BS in air was O₂-dependent and was the result of damages to coat proteins of the phage caused by the free radicals generated from BS and O₂. (29 refs)

- 79-0677 Quantitative Analyses of Radiation- and Chemical-induced Lethality and Mutagenesis in Chinese Hamster Ovary Cells.** (Eng) Hsie, A. W. (Biology Div., Univ. Tennessee, Oak Ridge Graduate Sch. Biomedical Sciences, Oak Ridge, TN, 37830); O'Neill, J. P.; Couch, D. B.; SanSebastian, J. R.; Brimer, P. A.; Machanoff, R.; Fuscoe, J. C.; Riddle, J. C.; Li, A. P.; Forbes, N. L.; Hsie, M. H. *Radiat Res* 76(3): 471-492; 1978.

A Chinese hamster ovary cell/hypoxanthine-guanine phosphoribosyl transferase (CHO/HGPRT) mutational assay was developed as a method for inducing and selecting 6-thioguanine (TG)-resistant mutants that are affected almost exclusively at the HGPRT locus. Ethyl methanesulfonate was used to illustrate the concentration-dependent interrelationships of cellular lethality and induced mutation and to study the structure-activity relationships of alkylating agents and heterocyclic nitrogen mustards. With all chemical mutagens studied, mutation induction increased linearly as a function of concentration with an apparent threshold effect. The mutagenicity of 79 physical and chemical agents, 42 of which were known to be carcinogenic or noncarcinogenic, was tested. Of 42 compounds with reported carcinogenicity in animal tests, 40 were mutagenic in the CHO/HGTRP assay. Fluorescent white, black, and blue lights were weakly lethal and mutagenic in the system; sun and sunlamp light were highly lethal and mutagenic; UV light induced mutations linearly from 2 to 27 J/m². The assay is recommended as a model system for studying the mechanisms of mammalian cell mutagenesis and as a short-term assay for screening environmental mutagens and carcinogens. (44 refs)

- 79-0678 Differential Sensitivity of DNA Replication and Repair in Permeable *Escherichia coli* Exposed to Various Monofunctional Methylating or Ethylating Agents.** (Eng) Hellermann, G. R. (Univ. Tennessee-Oak Ridge Graduate Sch. Biomedical Sciences, Oak Ridge, TN, 37830); Billen, D. *Chem Biol Interact* 23(3): 305-314; 1978.

The effects of various chemical alkylating agents on the replication and repair of DNA were investigated using *Escherichia coli* cells made permeable to deoxynucleoside triphosphates by brief treatment with toluene. Compounds employed included methyl methanesulfonate (MMS), ethyl methanesulfonates (EMS), N-methyl-N-nitrosourea (MNU), N-ethyl-N-nitrosourea (ENU), N-methyl-N'-nitro-N-ni-

trosoguanidine (MNNG), and N-ethyl-N'-nitro-N-nitrosoguanidine (ENNG). Results revealed that replication of DNA was completely inhibited 10-15 min after exposure to MMS (5 mM or more), or MNU or MNNG (1 mM or more). Ethyl derivatives were less inhibitory than their methyl counterparts, with replication inhibition occurring in the following order: EMS < ENNG < ENU. Maximum replication inhibition occurred at a concentration of 20 mM or less for all compounds tested except EMS, which showed increasing activity up to the highest concentration tested (100 mM). Polymerase I (Pol I)-directed DNA repair synthesis (induced by x-irradiation) was reduced 40% by MNNG treatment (20 mM) and 30% by ENNG treatment (20 mM). ENU was slightly inhibitory to Pol I activity, while MMS, EMS, and MNU all resulted in slightly enhanced activity. It is concluded that DNA replication in this pseudo-in vivo bacterial system is very sensitive to the effects of known chemical mutagens, while DNA repair carried out by the Pol I repair enzyme is much less sensitive, and in some cases, unaffected. (16 refs)

- 79-0679 Carcinogenic Potential of Hycanthone in Mice and Hamsters.** (Eng) Bulay, O. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd St. and Dewey Ave., Omaha, NB, 68105); Urman, H.; Patil, K.; Clayson, D. B.; Shubik, P. *Int J Cancer* 23(1): 97-104; 1979.

The carcinogenicity of hycanthone was determined following ip or im injection in amounts up to the max tolerated dose (80 mg/kg/wk) into *Schistosoma mansoni*-infected and uninfected Syrian golden hamsters and Swiss mice. Hycanthone treatment did not affect the survival of the mice, although the survival of the infected hamsters was somewhat decreased due to an outbreak of "wet tail." No tumors attributable to treatment were observed in the hamsters, and the only tumors that increased in hycanthone-treated mice compared to controls were hepatomas and hepatocellular carcinomas (overall incidence 3.4% in infected controls, 10.6% in infected hycanthone-treated mice, 0.8% in uninfected controls, and 10.2% in uninfected hycanthone-treated mice). Statistical significance was attained only in the case of uninfected female mice injected ip and im with hycanthone, and then only at confidence levels of 92% and 95%, respectively. The results indicate that hycanthone is, at most, a very weak carcinogen for mouse liver and is inactive in hamsters. (30 refs)

- 79-0680 Microdetermination of Silicon in Blood, Serum, Urine, and Milk Using Furnace Atomic Absorption Spectrometry.** (Eng) Lo, D. B. (Dept. Pediatrics, Univ. Cincinnati Medical Center, Cincinnati, OH, 45267); Christian, G. D. *Microchem J* 23(4): 481-487; 1978.

A direct microanalytical method for the quantitative determination of silicon in human whole blood, serum, urine, and milk by furnace atomic absorption spectrometry is described.

The method combines atomic absorption analysis with the use of a heated graphite tube atomizer for the determination of silicon in microliter samples. The sensitivity is 1.3 nanograms. Silicon was found to be generally more concentrated in human blood than in serum by a factor of about 2. (16 refs)

- 79-0681 Inhibition of Azoxymethane-induced Intestinal Cancer by Disulfiram.** (Eng) Nigro, N. D. (Dept. Surgery, Wayne State Univ. Sch. Medicine, Detroit, MI, 48201); Campbell, R. L. *Cancer Lett* 5(2): 91-95; 1978.

A study was made of the effect of disulfiram (DS: 0.25% of diet) on intestinal tumor formation in intact and colostomized male Sprague-Dawley rats treated with azoxymethane (AOM: 8 mg/kg/wk for 24 wk, sc). The av numbers of small and large intestinal tumors per intact rat was significantly reduced by DS from 6.3 to 0.95. Furthermore, the number of rats developing tumors was reduced from 100% to 60%. In colostomized animals, DS reduced the number of tumors per rat from 5.0 to 0.13. There were no tumors in the small intestine and functional colon of these rats, and the number of tumors in the defunctionalized colon was reduced 25-fold. All tumors examined were adenocarcinomas. It appears that DS inhibits intestinal carcinogenesis with AOM by interrupting its metabolism to methylazoxymethanol and that this action is systemic. (7 refs)

- 79-0682 A Test of the Carcinogenicity of Enflurane, Isoflurane, Halothane, Methoxyflurane, and Nitrous Oxide in Mice.** (Eng) Eger, E. I. (Dept. Anesthesia, Univ. California, San Francisco, CA, 94143); White, A. E.; Brown, C. L.; Biava, C. G.; Corbett, T. H.; Stevens, W. C. *Anesth Analg (Cleve)* 57(6): 678-694; 1978.

The carcinogenic potential of enflurane, isoflurane, halothane, methoxyflurane, and nitrous oxide in air or in O₂ was tested in Swiss ICR mice. The mice were given 2-hr exposures to 1/32, 1/8, and/or 1/2 max allowable concentration (MAC) of the compounds both in utero (on gestation days 11, 13, 17, and 19) and after delivery (24 exposures at 2- to 3-day intervals beginning on postnatal day 5). In all, 1973 mice were sacrificed at 9 or 15 mo of age and examined for tumor development. Neoplastic lesions, mainly pulmonary adenomas, lymphomas, hepatocyte lesions, and liver vascular lesions, were found in all treatment and control groups, and although a few relationships of statistical significance were discovered in the large number of comparisons made, there was no consistent relationship noted with any anesthetic agent or dose. For example, male mice receiving 1/2 MAC isoflurane or 1/2 MAC halothane in air had a higher incidence of pulmonary adenomas and a significantly lower incidence of lymphomas than their air controls, but male mice given the same anesthetics and doses in an O₂ background did not differ from their O₂ controls. The results do not confirm the suggestion that isoflurane is a hepatocarcinogen and

they do not suggest that modern inhaled anesthetics pose a significant threat of carcinogenicity. (29 refs)

- 79-0683 Tissue-mediated Mutagenicity of Vinylidene Chloride in *Salmonella typhimurium* TA1535.** (Eng) Jones, B. K. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Cheshire, SK10 4TJ, England); Hathway, D. E. *Cancer Lett* 5(1): 1-6; 1978.

The Ames' mutagenicity assay, modified to assess the mutagenicity of gases and vapors, was used to assess the mutagenic potential of vinylidene chloride (VDC) when incubated with a fortified mammalian kidney or liver tissue postmitochondrial supernatant (S-9 mix) from various species. Seeded dishes of *Salmonella typhimurium* strain TA100 or TA1535 were exposed to an atmosphere of 5% VDC in air for 72 hr. TA100 and TA1535 gave similar results. VDC was strongly mutagenic when mediated by mouse kidney (23-fold increase in mutation frequency) and liver (18-fold increase) S-9 mix from Aroclor 1254 induced animals. VDC was weakly mutagenic when mediated by S-9 mix from uninduced mouse kidney (2.3-fold increase) and liver (1.6-fold increase). VDC was weakly positive (5-fold) when mediated by liver S-9 mix from similarly induced rats, but it was not mutagenic (≤ 1.2 -fold) when mediated by kidney or liver S-9 mix from noninduced rats. VDC showed weak mutagenicity (3-fold) when tested in a system mediated by liver S-9 mix from a human who had received long-term phenobarbital medication, but it was not mutagenic when mediated liver S-9 mix from noninduced marmosets or a noninduced human. Thus, the mutagenic potential of VDC depends considerably on the degree of activation of relevant drug-metabolizing enzymes. The results agree with the greater availability in treated mice than in rats of the reactive VDC metabolites 1,1-dichloroethylene oxide and chloroacetyl chloride and with the VDC carcinogenicity found in mice but not in rats. The data suggest that the limited number of primates examined respond more like rats than mice with regard to generation of alkylating metabolites and their reaction with bacterial DNA. (10 refs)

- 79-0684 Vinylchloride Sorption by Dry Casein Particles: Mechanistic Considerations.** (Eng) Biran, D. (Bait Yizzhak, Israel); Giacin, J. R.; Hayakawa, K.; Gilbert, S. G. *J Food Sci* 44(1): 59-61; 1978.

The amount of vinyl chloride monomer (VCM) sorbed by dry casein particles increases with a decrease in temperature or a reduction in moisture content of the particles. Adsorption is presumed to take place on the casein surface and to involve two distinctly different modes of sorption: active site sorption in which VCM molecules are attracted to the casein surface and an intermolecular attraction of VCM molecules, in which there is clustering around initially bound VCM. (10 refs)

- 79-0685 Study of Cocarcinogenic Effect of Polyvinyl Chloride and 20-Methylcholanthrene.** (Bul) Draganov, I. (Res. Inst. Oncology, Sofia, Bulgaria); Raichev, R.; Radeva, M. *Onkologiya* 15(3): 132-137; 1978.

The cocarcinogenic effect of polyvinyl chloride (PVC) and 20-methylcholanthrene (20-MC) was studied in random-bred rats. PVC plates were implanted in the animals and, 30 days later, the animals were inoculated with 20-MC (10 mg in 0.5 ml of sunflower oil, sc). The av latent period of tumor development was 2-5 mo, compared with 16-20 mo in animals exposed to PVC alone. The av latent period of tumor development in rats treated with 20-MC alone was also 2-5 mo. Tumor incidence was 17.5%-20% in rats exposed to PVC alone, 42% in rats treated with 20-MC alone, and 68% in rats exposed to PVC + 20-MC. (9 refs)

- 79-0686 Mutagenicity Studies with X-Ray-Contrast Media, Analgesics, Antipyretics, Antirheumatics and Some Other Pharmaceutical Drugs in Bacterial, Drosophila and Mammalian Test Systems.** (Eng) King, M. T. (Zentrallaboratorium für Mutagenitätsprüfung, Deutschen Forschungsgemeinschaft, Breisacher Strasse 33, Freiburg, W. Germany); Beikirch, H.; Eckhardt, K.; Gocke, E.; Wild, D. *Mutat Res* 66(1): 33-43; 1979.

Twenty-one frequently sold pharmaceuticals (6 organic x-ray-contrast media; 13 analgesics, antipyretics, and antirheumatics; 1 CNS stimulant; and 1 antidepressant), were tested for mutagenicity in several test systems. These consisted of the *Salmonella typhimurium* mutagenicity assay using strains TA1535, TA100, TA1538, TA98, and TA1537, each with and without liver homogenate activation; the *Escherichia coli* mutagenicity assay with and without liver homogenate activation, the host-mediated assay using *E. coli* and female NMRI mice; the sex-linked recessive lethal test in *Drosophila melanogaster*, and the micronucleus test with male and female NMRI mice. Four of the 21 compounds gave positive results: 1,2-dichloroethane in *Drosophila*, quinine dihydrochloride and dimethylaminophenazone in *S. typhimurium* TA98 in the presence of a liver homogenate derived from Aroclor-induced rats, and trilithium citrate in the micronucleus test. The apparent lack of correlation between the results obtained with these procedures cannot be explained, nor can the success or failure of the procedures be judged. However, the results do indicate an urgent need for further studies of the mutagenic effects of the four positive drugs. (36 refs)

- 79-0687 Role of Liver in the Development of Dysfunctional Diseases of the Mammary Gland in Rats.** (Rus) Ird, E. A. (Lab. Carcinogenic Agents, Cancer Res. Center, Moscow, USSR); Smirnova, I. O. *Biull Eksp Biol Med* 86(12): 713-715; 1978.

To evaluate the role of liver in the development of dysfunctional diseases of the mammary gland, random-bred female rats were subjected to sc injections with CCl₄ (0.01 ml/100 g, 2x/wk for 6 mo, with a 2-wk and a 3-wk interruption of treatment at 3 and at 8 wk, respectively after the initiation of the experiment). Animals were divided into four groups: Group 1 included 3.5- to 4-mo-old rats, Group 2 consisted of 12-mo-old rats, Group 3 included 3- to 4-wk-old rats with follicular cysts induced by constant lighting, and Group 4 consisted of 10- to 12-mo-old rats with permanent estrus. Contrary to the previously reported data on the increased incidence of mastopathy and mammary gland tumors after continuous exposure to CCl₄, the discrete administration of the hepatocarcinogen had marked preventive effect. In group 1, CCl₄ administration increased the latent period of mastopathy development from 7 mo (in controls) to 10 mo, and of mammary gland tumors (fibroadenomas) from 9.5 to 13 mo (the incidence of mastopathy and tumors in treated rats was 28% and 5%, respectively, compared with 26% and 5% in controls). Rats in Group 2 had significantly decreased incidence of mastopathy (37%, compared with 74% in controls), while the incidence of fibroadenomas was similar in treated and control animals (16%). In Group 3, CCl₄ administration resulted in a marked decrease in the incidence of follicular cysts (2%, compared with 81% in rats exposed to lighting alone and a significant decrease in the incidence of mastopathy (3% versus 74%) and of fibroadenomas (1% versus 11%). The minimal latent period of follicular cyst development increased from 1.5 mo in rats exposed to lighting alone to 9 mo in rats exposed to lighting and CCl₄. In Group 4, CCl₄ administration decreased the incidence of follicular ovarian cysts (55%, compared with 91% in controls) and of mastopathies (41% versus 91%), but did not affect the incidence of fibroadenomas (22% and 21%, respectively, in treated and control animals). These findings might indicate that the regression of CCl₄-induced cirrhosis can cause normalization of estrogen function. (10 refs)

- 79-0688 Carcinomas of the Liver in Osborne-Mendel Rats Ingesting DDT.** (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD, 21501). *Tumori* 64(6): 571-577; 1978.

DDT (1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane) carcinogenesis was studied in male and female Osborne-Mendel rats given 0-800 ppm DDT in corn oil and 600 or 800 ppm dry DDT in the feed for 2 yr. Rats given the higher doses of DDT developed tremors and experienced growth retardation. DDT at 400-800 ppm caused increased mortality in the females but did not affect mortality in the males. Liver size was increased in females given ≥ 200 ppm and in males given ≥ 400 . Hepatocellular carcinomas of the liver developed in 6/21 males (mostly in those given 800 ppm) and 3/12 females (given 200-600 ppm). Neoplastic nodules developed in the livers of four males, and a Kupffer cell sarcoma developed in one male. The first liver carcinomas appeared after 84 wk of DDT treatment. Other neoplasms included lung lym-

phosarcomas in 13 males, a lymphosarcoma of the spleen in 1 male, and carcinomas of the ovary in 11 females. (37 refs)

- 79-0689 Lack of Mutagenicity of Two Possible Metabolites of Halothane.** (Eng) Waskell, L. (Dept. Biochemistry, Univ. California, Berkeley, CA, 97420). *Anesthesiology* 50(1): 9-12; 1979.

Two probable halothane metabolites, 1,1-difluoro -2-bromo-2-chloroethylene and 1,1,1-trifluoro -2-chloroethane, were nonmutagenic in the Ames *Salmonella*/mammalian liver system. (18 refs)

- 79-0690 Oral Mucosal White Lesions Associated with Excessive Use of Listerine Mouthwash.** (Eng) Bernstein, M. L. (Dept. Oral Pathology/Pathology Sch. Dentistry, Univ. Kentucky Health Sciences Center, Louisville, KY, 40232). *Oral Surg* 46(6): 781-785; 1978.

Two cases are reported in which Listerine mouthwash induced white, diffuse lesions after prolonged surface contact. In one case, a 68-yr-old white man had filmy, translucent, white lesions affecting the lateral buccal and labial mucosa as well as the sulchi, crenulous ridges, and the floor of the mouth. A fissured pattern became apparent upon stretching, showing nonulcerated, linear, pink, parallel fissures interrupting the confluent white patches. In the second case, a 34-yr-old Indian man also showed diffuse, filmy, fissured or corrugated white lesions. The lesions could not be scraped off in either man, and they both admitted exorbitant use of Listerine. After discontinuing use of the mouthwash for 2 wk, the lesions disappeared in both cases. It appears that the changes were hyperkeratosis or acanthosis, resulting as a protective response to the low-grade chronic irritation, or coagulation of epithelial proteins as a result of the caustic exposure. The importance of this observation resides in the fact that the identification of these lesions allows separation from the idiopathic white lesions indicative of cancer. Moreover, if the aggravating constituent of the mouthwash is alcohol, this could have implications regarding the known role of alcohol as a cocarcinogen in oral cancer. (12 refs)

- 79-0691 Sorption of Vinylchloride by Selected Food Constituents.** (Eng) Biran, D. (Bait Yizhak, Israel); Gilbert, S. G.; Giacini, J. R. *J Food Sci* 44(1): 56-58; 1978.

The sorption of vinyl chloride monomer for selected food constituents (water, corn oil, oil-in-water emulsions, casein, and sucrose) was found to be affected significantly by the chemical nature of the food constituent, the initial concentration of VCM, and temperature. (12 refs)

- 79-0692 Ethylene Dibromide in Urban Air.** (Eng) Leinster, P. (Public Health and Water Resource Engineering Section, Imperial Coll. Science and Technology, London S.W.7, England); Perry, R.; Young, R. J. *Atmospheric Environment* 12(12): 2383-2387; 1978.

A procedure for the rapid sampling of ethylene dibromide, a potential carcinogen, in ambient air is described. Ambient levels in London air were in the range 0.001-0.17 $\mu\text{g}/\text{m}^3$, and levels on a garage forecourt were 1.2 and 1.8 $\mu\text{g}/\text{m}^3$. Ethylene dibromide was also measured in car exhaust, a calculation relating levels of organic lead to those of ethylene dibromide is presented. (9 refs)

- 79-0693 Simple and Rapid Determination of Epichlorohydrin at the Lower Parts per Billion Level by Gas Chromatography-Mass Fragmentography.** (Eng) Van Lierop, J. B. (Food Inspection Service, Nijenoord 6, Utrecht, Netherlands). *J Chromatogr* 166(2): 609-610; 1978.

A method for the determination of epichlorohydrin, based on gas chromatography-mass fragmentography, is described. The method is highly sensitive (to 6 ppb) and specific. (3 refs)

- 79-0694 The Influence of Contaminants on the Mutagenic Activity of Dibromochloropropane (DBCP).** (Eng) Biles, R. W. (Div. Environmental Toxicology, Dept. Preventive Medicine and Community Health, Univ. Texas Medical Branch, Galveston, TX, 77550); Connor, T. H.; Trieff, N. M.; Legator, M. S. *J Environ Pathol Toxicol* 2(2): 301-312; 1978.

The causative agent(s) and mechanism of mutagenic activity of technical grade (TG) 1,2-dibromo-3-chloropropane (DBCP) were investigated in the Ames mutagenesis test using *Salmonella typhimurium* TA1535. Without metabolite activation, TG DBCP was weakly mutagenic in the concentration range 50-1,000 $\mu\text{g}/\text{plate}$, whereas pure DBPC showed little or no mutagenicity in the same concentration range. Purification of the TG compound by distillation resulted in a first distillate with more than two-fold greater mutagenicity than the TG compound and a second distillate with mutagenicity similar to that of the TG compound. The first distillate was found to contain epichlorohydrin (ECH), which was present in the TG compound in an amount close to 1.5% by wt, as well as an unidentified compound. The second distillate contained smaller amounts of both compounds. The amount of ECH in the TG sample was calculated for each dose level tested, and the number of revertants obtained in tests of this sample could be attributed solely to the calculated amount of ECH in each test dose. Both TG and pure DBCP were strongly mutagenic in the concentration range 20-200 $\mu\text{g}/\text{plate}$ after S-9 metabolic activation. Results similar to those of the Ames test were obtained using a desiccator tech-

nique. The data indicate that in the direct in vitro evaluation, the mutagenicity of DBCP can be attributed almost entirely to the addition of the stabilizer ECH. (22 refs)

79-0695 Induction of Pulmonary Adenomas in Strain A Mice by Substituted Organohalides. (Eng)

Theiss, J. C. (Dept. Community Medicine, Sch. Medicine, Univ. California, La Jolla, CA, 92093); Shimkin, M. B.; Poirer, L. A. *Cancer Res* 39(2, Part 1): 391-395; 1979.

An investigation was made of the abilities of 28 organohalides (10 monochlorinated and 18 monobrominated derivatives of alcohols, esters, ethers, carboxylic acids, ketones, and amines that contained 2-4 carbon atoms) to induce lung adenomas in strain A mice. Groups of 20 mice (10 males, 10 females) received ip injections 3x/wk of either the max tolerated dose (MTD), 0.5 MTD, 0.25 MTD, or 0.20 MTD. Except for the more toxic compounds, 24 injections were given when possible. The mice were sacrificed 24 wk after the first injection and their lungs examined. 2-Chloro-N,N-dimethylethylamine hydrochloride, 3-chloropropionic acid, 4-chloro-1-butanol, and 2-bromoethanol produced an elevated pulmonary adenoma response that was significant by two different statistical tests. These substituted derivatives appeared to exert tumorigenic activity at lower doses than those of similar unsubstituted compounds (previous data); thus, nucleophilic substitution may increase the tumorigenicity of linear alkyl halides. Ethyl chloroacetate, 3-chloropropene, 3-chlorobutyric acid, 3-bromopropionic acid, and 3-bromopropylamine hydrobromide produced an elevated lung tumor response that was significant by only one of the statistical tests used. These compounds thus had borderline tumorigenicity in this bioassay. Four of the organochlorides and 15 of the organobromides showed no significant tumorigenicity. Among the negative compounds were three acylating agents, isobutyl bromide, butyl bromide, and benzoyl bromide. In general, the MTD's of the organobromides were substantially lower than those of the organochlorides. The finding that a greater percentage of the chloro compounds showed tumorigenicity than did the bromo derivatives was unexpected, based on chemical activity and on previous studies of mutagenicity and carcinogenicity among organohalides. The greater toxicity of the organobromides toward strain A mice may mask their potential tumorigenicity in some cases, as these compounds could not be administered in sufficient amounts to induce tumor formation. (14 refs)

79-0696 A Quantitative Dosing Schedule for the Induction of Transitional Cell Carcinomas in Female F344 Rats with the Use of N-Butyl-N-(4-hydroxybutyl)nitrosamine. (Eng) Becci, P. J. (Life Sciences Div., ITT Res. Inst., 10 W. 35th St., Chicago, IL, 60616); Thompson, H. J.; Grubbs, C. J.; Moon, R. C. *J Natl Cancer Inst* 62(1): 187-191; 1979.

The use of female rats avoids the complication of bladder stones, which are more frequent in males. Transitional cell carcinoma (TCC) of the urinary bladder was induced in female F344 rats by N-butyl-N-(4-hydroxybutyl)nitrosamine (OH-BBN), using a quantitative dosing schedule. Animals received 100, 150, or 200 mg OH-BBN by gastric intubation 2x/wk for 6 wk to a total dose of 1,200, 1,800, or 2,400, respectively, and they were sacrificed and examined for tumor growth at 6 and 12 mo after the first intubation. The diagnosis of TCC was determined by invasion of the underlying connective tissue or smooth muscle. Varying degrees of squamous and/or glandular metaplasia were observed in many of the TCC. Proliferative epithelial lesions included discrete hyperplastic lesions and noninvasive papillomas that did not meet the diagnostic criteria for carcinoma. At 6 mo, 20%, 60%, and 60% of the animals presented with TCC and 50%, 40%, and 40% exhibited discrete proliferative lesions with atypical epithelium (cellular atypia score $\geq +2$ on a scale of 0 to +5) at the respective doses. At 12 mo, the incidence of TCC was 90%, 80%, and 100% that of discrete proliferative lesions with atypical epithelium, 10%, 10%, and 13%, respectively. These data suggest that the lesions observed at 6 mo progressed to TCC by 1 yr and that the period of time after OH-BBN instillation rather than dose per se was the predominant factor in determining TCC incidence. Apparently, the two higher doses served only to reduce tumor latency and were in excess of the dose required to induce a high TCC incidence by 1 yr. (18 refs)

79-0697 Phenobarbital Stimulation of Cytochrome P-450 and Aminopyrine N-Demethylase in Hyperplastic Liver Nodules During DL-Ethionine Carcinogenesis. (Eng) Feo, F. (Cattedra di Patologia generale II dell'Universita Via Mancini, 1 Sassari, Italy); Canuto, R. A.; Garcea, R.; Brossa, O.; Caselli, G. C. *Cancer Lett* 5(1): 25-30; 1978.

The decrease of cytochrome P-450 (C/P-450) levels and aminopyrine N-demethylase (ADM) activity in hyperplastic nodules (HPN) and hepatomas induced by DL-ethionine, as associated with an impaired response to phenobarbital (PB) stimulation, was investigated. Male Wistar rats were fed a basal diet supplemented with 0.25% DL-ethionine for 5.5 mo, followed by basal diet only. At 7-9 mo after feeding initiation, some of the animals were injected ip with PB (80 mg/kg at 72 hr and 40 mg/kg at 48 and 24 hr before sacrifice). Liver tissue surrounding the nodules, HPN, and hepatomas were analyzed for amount of microsomal protein, C/P-450, and ADM. In rats not treated with PB, microsomes isolated from DL-ethionine-induced HPN and hepatomas had reduced C/P-450 levels and ADM activity compared with the organelles of control and surrounding liver. The values for the hepatoma were uniformly lower than those for the HPN. In addition, microsomal protein levels were 25%-28% higher in the HPN and 27%-30% lower in the hepatomas. PB administration increased the amount of microsomal protein, C/P-450, and ADM in all tissues tested. In the hepatomas,

the increase in C/P-450 and ADM per gram of tissue was very low and was compensated by a slight increase in microsomal protein. In HPN and in control and surrounding livers, C/P-450 and ADM increased more than microsomal protein, but the activity of PB was significantly lower in HPN than in control and surrounding livers. The inability of PB to greatly stimulate the monooxygenase system in HPN could be advantageous, in view of the fact that many carcinogens and hepatotoxic drugs are inducers of various constituents of this system. - 79-0698 Concanavalin A Agglutination of Bladder Cells of Rats Treated with Bladder Carcinogens; A Rapid New Test to Detect Bladder Carcinogens.** (Eng) Karkizoe, T. (Urology Div., Natl. Cancer Center Hosp., Tokyo, Japan); Kawachi, T.; Okada, M. *Cancer Lett* 5(5): 285-290; 1978.

The agglutination by concanavalin A (Con A) of isolated bladder mucosa cells from male Wistar rats treated with N-butyl-N-(4-hydroxybutyl) nitrosamine (BBN) or five of its analogs was investigated. Equimolar concentrations of the compounds were administered in drinking water for 1 wk, at which time animals were sacrificed and bladder mucosa cells isolated by treatment with EDTA and sonication. The agglutination assay was performed in a final volume of 40 μ l phosphate-buffered saline containing 2.5×10^6 cells/ml and 200 or 400 μ g/ml Con A, with or without 10 μ g/ml α -methyl mannoside. Cells treated with BBN (total dose 110 mg), N-butyl-N-(3-carboxypropyl)nitrosamine (115 mg), N-ethyl-N-(4-hydroxybutyl)nitrosamine (112 mg), and N-butyl-N-(2-hydroxyethyl)nitrosamine (115 mg) were positive, but cells treated with N-tert-butyl-N-(4-hydroxybutyl)nitrosamine (124 mg) and N-butyl-N-(3-hydroxypropyl)nitrosamine (101 mg) were negative. These results correlated well with the known carcinogenicity and mutagenicity of these compounds. Therefore, this method could provide a new rapid system for detecting potential bladder carcinogens. (22 refs)

- 79-0699 Aliphatic 3,4 Epoxyalcohols: Metabolism by Epoxide Hydrase and Mutagenic Activity.** (Eng) Ortiz de Montellano, P. R. (Dept. Pharmaceutical Chemistry, Sch. Pharmacy, Univ. California, San Francisco, CA, 94143); Boparai, A. S. *Biochim Biophys Acta* 544(3): 504-513; 1978.

The enzymatic hydrolysis of aliphatic epoxides bearing a vicinal hydroxyl group was investigated as part of a search for biologically significant intramolecular interactions of epoxides with other functional groups. Various substrates were incubated with rabbit hepatic microsomal suspensions equivalent to 1.0 g of intact liver for 30 min-2 hr under anaerobic conditions. Enzymatic hydrolysis of 1,2-epoxy-4-heptanol (I) gave a high yield of 1,2,4-heptanetriol. Both diastere-

omers of the substrate were hydrolyzed at comparable rates, since an equal mixture of the two was completely converted within 1 hr into an equal mixture of the two product diastereomers. Incubation of cis- or trans-3,4-epoxy-1-hexanol with liver microsomes yielded 1,3,4-hexanetriol, but at a relatively low rate. The trans isomer gave exclusively one diastereomer (erythro) of the triol, but the cis isomer gave the other diastereomer (threo). The product expected if a primary cationic intermediate were to be formed and trapped intramolecularly during the hydrolysis of Compound I, 2-propyl-4-tetrahydrofuranol, was not observed. A comparison of the mutagenic activity of 1-heptene, 1-hepten-4-ol, 1,2-epoxyheptane and I to *Salmonella typhimurium* TA100 revealed that only the latter is a detectable mutagen. Apparently, hydrogen bonding between the epoxide and the vicinal hydroxyl group does not interfere seriously with the hydrolytic mechanism of epoxide hydrazes, but it does enhance the bioalkylating potential of an otherwise unactivated aliphatic system. (31 refs)

- 79-0700 Alterations in *Bacillus subtilis* Transforming DNA Induced by β -Propiolactone and 1,3-Propane Sultone, Two Mutagenic and Carcinogenic Alkylating Agents.** (Eng) Kubinski, Z. O. (Div. Neurosurgery, Univ. Wisconsin, Madison, WI, 53706); Kubinski, H. *J Bacteriol* 136(3): 854-866; 1978.

The genetic properties of transforming DNA altered by either β -propiolactone (BPL) or 1,3-propane sultone (PS) treatment were studied. Transforming DNA from *Bacillus subtilis* was exposed to 50 mM BPL or PS and then used for transformation of competent bacteria to nutritional independence from tyrosine and tryptophan (linked markers) and leucine (an unlinked marker). The transforming ability of DNA was progressively lost during incubation with either chemical. For all three markers, the inactivation curve was biphasic, with a short period of rapid inactivation followed by one characterized by a much slower rate. The overall inactivation rate was different for all three markers and was presumably related to the size of the marker. The decrease in the transforming activity was in part due to the slower rate of penetration of alkylated DNA through the cellular membrane and its inability to enter the recipient bacteria. This decrease in the rate of cellular uptake, even for DNA eventually destined to enter the cell, began almost immediately after its exposure to the chemical and ultimately almost completely lacked recognition of the heavily alkylated DNA by the specific surface receptors of competent cells. Such DNA attached to sites on the surface of competent bacteria that were different from receptors specific for the untreated nucleic acid. This attachment was not followed by uptake of the altered DNA. The presence of albumin during the incubation with a carcinogen further increased the degree of inactivation, indicating that the artificial nucleoproteins produced under such conditions were less efficient in the transformation assay than was the naked DNA. Cotransformation of close markers progressively decreased, beginning immediately after the start of incubation of DNA with the chemicals. Extensively alkylated DNA

fractionated by sedimentation through sucrose density gradients showed a peculiar distribution of cotransforming activity for such markers; namely, molecules larger than the bulk of DNA ("megamolecules") showed less ability to transform the second marker than did some of the apparently smaller molecules that sedimented more slowly through the gradient. An increase in cotransformation of distant markers was evident in DNA molecules after a short exposure to an alkylating agent, but cotransformation of such markers did not occur in DNA treated for longer periods. The changes in the transforming and cotransforming activities of the alkylated DNA can be explained by knowledge of the physicochemistry of such DNA and in particular about the propensity of the alkylated and broken molecules to form complexes with themselves and with other macromolecules. - 79-0701 Mutagenicity of Chlorinated Cyclopentadienes due to Metabolic Activation.** (Eng) Goggelman, W. (Dept. Toxicology, Gesellschaft für Strahlen-und-Umweltforschung, 8042 Munich-Neuherberg, W. Germany); Bonse, G.; Henschler, D.; Creim, H. *Biochem Pharmacol* 27(24): 2927-2929; 1978.

In an *Escherichia coli* K12 (343/113) mutagenicity test, the chlorinated cyclopentadienes tetrachlorocyclopentadiene and pentachlorocyclopentadiene were highly mutagenic after metabolic activation with mouse liver microsomes, whereas hexachlorocyclopentadiene (HCCP) was not. Metabolic insertion of oxygen into the C-1 position of HCCP is apparently hindered by the presence of two chlorine atoms, whereas no or only one chlorine atom at this position permits oxygen insertion. (15 refs)

- 79-0702 Comments on the Significance of Quasi-valence Number for Chemical Carcinogenesis.** (Eng) Lyle, R. E. (Dept. Chemistry, North Texas State Univ., Denton, TX, 76203); Lyle, G. G. *Experientia* 34(12): 1653-1654; 1978.

A number of examples are given to demonstrate that the quasi-valence number of a compound is not a useful criterion of carcinogenicity because it does not provide a structural screen capable of eliminating a large number of noncarcinogenic compounds while identifying most of the active ones. (3 refs)

- 79-0703 Short-Term Tests for Carcinogenesis. Evaluation, Predictive Values, Various Strategies.** (Fre) Bedouelle, H. (Laboratoire de Toxicologie genetique, Institut Pasteur, 28, rue du Docteur-Roux, 75015 Paris, France); Hofnung, M. *C R Acad Sci D (Paris)* 287: 891-894; 1978.

Statistical requirements for evaluating the Ames (*Salmonella typhimurium*) assay for testing carcinogens are discussed. Mathematical formulas of the relationship between evaluation of an agent by the Ames test and the predictive value of the test are presented. (7 refs)

- 79-0704 Screening for Carcinogens in the Working Environment.** (Dan) Olsen, J. (Smedebakken 10, 5270 Odense N., Denmark). *Ugeskr Laeger* 140(51): 3248-3249; 1978.

The value of Ames mutagenicity test in screening carcinogens in the working environment is discussed. Positive Ames tests have little predictive value, but it is highly probable that substances for which the test is negative are noncarcinogenic. (2 refs)

- 79-0705 Relation among Occupational Exposure to Potential Mutagenic/Carcinogenic Agents, Clinical Findings, and Bone Marrow Chromosomes in Acute Nonlymphocytic Leukemia.** (Eng) Mitelman, F. (Dept. Clinical Genetics, Univ. Hosp., S-221 85 Lund, Sweden); Brandt, L.; Nilsson, P. G. *Blood* 52(6): 1229-1237; 1978.

Chromosome findings in acute nonlymphocytic leukemia patients were correlated with occupational exposure to potentially leukemogenic chemicals. The chromosome banding pattern of bone marrow cells and clinical findings, including cytologic diagnosis, response to therapy, and survival time, were compared in two groups of adult ANLL patients: 23 occupationally exposed to chemical solvents, insecticides, and petroleum products and 33 with no history of occupational exposure to potential mutagenic/carcinogenic agents. As regards clinical findings, cases classified as acute myeloid leukemia were more common in the exposed group, whereas the monocytic varieties of ANLL were more common in the nonexposed group. Neither the complete remission rate nor the median survival differed significantly. In both groups, patients with only abnormal metaphases had poorer prognoses than those with normal bone marrow metaphases only. The detailed karyotypic findings showed striking differences between the two groups: (1) in the nonexposed group, only 24.2% had chromosome aberrations, whereas 82.6% of the exposed patients had aberrations; (2) in the exposed group, 84.2% of the patients with aberrations had at least one of four particular changes--monosomy 5 or 7 or trisomy 8 or 21, but none of the nonexposed patients had monosomy 5 or trisomy 8, and only one patient had monosomy 7 and one had trisomy 21. None of the remaining aberrations seen in the nonexposed group were found in any of the exposed individuals. The results suggest that correlations might exist between leukemogenic agents, cytologic type of leukemia, and chromosome progression of the leukemic cells. (28 refs)

- 79-0706 Carcinogenicity of Kepone.** (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD, 21501). *J Toxicol Environ Health* 4(5/6): 895-911; 1978.

Five studies of the carcinogenicity of Kepone (chlordecone, or decachlorooctahydro -1,3,4- metheno-2H-cyclobuta(cd)pentalen-2-one) are reviewed. Examination of histological sections indicated that Kepone is carcinogenic in both rats and mice. In one study, it induced malignant tumors in the liver of rats and mice and in another study in the liver of rats. Malignant tumors were also found in other organs in high-dose male and female rats and in low-dose male rats. The tumors were related to the dose of Kepone ingested, with females being more susceptible than males. There were also toxic changes following Kepone ingestion, particularly in male rats. These changes (interstitial fibrosis of kidney, polyarteritis, atrophy of testes) generally interfered with health of the rats and with tumor development. In mice, males were somewhat more susceptible to the carcinogenic effects of Kepone than females. Histopathological findings in dogs fed Kepone (25 ppm) for up to 128 wk included necrosis around central veins in the liver, focal hyperplasia of the liver, thyroiditis, hyperplasia of the thyroid, and foci of atypical cells in the ovary. No conclusions can be drawn from this study, but changes in the liver, thyroid, and ovary probably would have progressed if Kepone ingestion had been continued for at least 6 yr. (7 refs)

- 79-0707 Alteration of Human Cellular DNA by Neutral Red in the Presence of Visible Light.** (Eng) Speck, W. T. (Dept. Pediatrics, Case Western Reserve Univ., Cleveland, OH, 44106); Santella, R. M.; Brem, S.; Rosenkranz, H. S. *Mutat Res* 66(1): 95-98; 1979.

The combined effect of neutral red (NR: 3-amino-7-dimethylamino-2-methylphenazine hydrochloride) and visible light on the DNA of human (KB) cells growing in tissue culture was studied. KB cells were incubated for 1 hr at 37 C with or without 1 µg NR/ml. Some of the cultures were subsequently illuminated with white light for a total dose of 2 kilojoules (kJ)/m². DNA was analyzed on alkaline sucrose gradients. Incubation of the cell in the dark in the presence of 1 µg NR/ml or in the light without NR had no effect on the DNA sedimentation profile. Illumination with kJ/M² in the presence of NR had a profound effect on the sedimentation characteristics of the DNA. The NR-induced photodegradation of the DNA was prevented to a large extent when illumination was carried out in the presence of 1,4-diazabicyclo(2.2.2)octane (DABCO), a substance that quenches singlet oxygen. Incubation of cells in complete medium following illumination in the presence of NR resulted in DNA repair, as evidenced by a return of the DNA to the high-mol-wt region of the gradient. These findings indicate that illumination of cells in the presence of NR results in repairable structural changes in cellular DNA. The results with DABCO

suggest that the alteration of the cellular DNA results from singlet oxygen. (34 refs)

- 79-0708 Metabolism of Triphenylmethane Colors (III). Comparison of Tissue Distribution and Biliary Excretion for ³H-Benzyl Violet 4B and ³H-Fast Green FCF (Food Green No. 3) in Rats.** (Eng) Minegishi, K. (Natl. Inst. Hygienic Sciences, 18-1 Kamiyama 1-chome, Setagaya-ku, Tokyo, Japan); Morimoto, K.; Yamaha, T. *Shokuhin Eiseigakuzasshi* 19(5): 482-485; 1978.

The distribution and biliary excretion of ³H-labeled Benzyl Violet 4B (BV: reported carcinogen) and Fast Green FCF (FG: noncarcinogen) were compared in female Sprague-Dawley rats administered 10 micromoles/kg of each dye po. The levels of BV in the plasma, ear, abdominal skin, and abdominal muscle were higher than those of FG, and the cumulative amounts of BV and FG excreted in the bile were 4.26% and 3.81% of the dose by 24 hr, respectively. The biological half-lives of BV in plasma and other tissues were significantly longer than those of FG. (9 refs)

- 79-0709 Azo Reduction of Trypan Blue to a Known Carcinogen by a Cell-free Extract of a Human Intestinal Anaerobe.** (Eng) Hartman, C. P. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Fulk, G. E.; Andrews, A. W. *Mutat Res* 58(2/3): 125-132; 1978.

A cell-free extract was prepared from *Fusobacterium* sp.2 and tested for its ability to reduce trypan blue. The incubation mixture contained 0.5 ml cell-free extract, 836 nanomoles of flavin mononucleotide (FMN), 33 micromoles of D-glucose-6-phosphate (Glc-6-P), 1 ml 0.1 M potassium phosphate buffer, and 2 micromoles of trypan blue. The inclusion of FMN and Glc-6-P was essential for max activity, but the presence of an exogenous NADPH generating system was not. Thin-layer chromatography and gas-liquid chromatography/mass spectroscopy showed that the product of trypan blue reduction by either the cell-free extract or sodium hydro-sulfite was o-tolidine, a known carcinogen. When this product and an equal amount of trypan blue were tested in the Ames' mutagenicity assay with *Salmonella typhimurium* strains TA1538 or TA98 in the presence of S-9 rat liver microsome mix, only the o-tolidine was mutagenic. It is suggested therefore that the teratogenic and oncogenic effects of trypan blue may be due to o-tolidine. (12 refs)

- 79-0710 A Case-Control Study of Hair Dye Use and Breast Cancer.** (Eng) Shore, R. E. (Inst. Environmental Medicine, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016); Pasternack, B. S.; Thiess-

en, E. U.; Sadow, M.; Forbes, R.; Albert, R. E. *J Natl Cancer Inst* 62(2): 277-283; 1979.

A case-control study of a possible association between hair dye use and subsequent development of breast cancer was made with the use of 129 breast cancer patients and 193 controls who had attended a multiphasic screening center between 1964 and 1976. All subjects were interviewed by telephone with regard to chronological time, duration, frequency, type, and color of hair dye used plus several risk factors associated with breast cancer. Incorporating the above use variables, measures of cumulative hair dye use at 0, 5, 10, and 15 yr prior to breast cancer development (or an equivalent time for controls) were determined. Confounding variables were controlled for by a multivariate risk factor score for each subject. The adjusted relative risks for breast cancer vs hair dye use always exceeded unity, but were generally not significant. After confounding variables were controlled, the integral measures (frequency x duration) were significantly related to breast cancer. Temporal pattern analysis showed that hair dye use ≥ 10 yr before cancer diagnosis was significantly related to the occurrence of the disease, suggesting that hair dyes act at some early stage of carcinogenesis and that the latency period is ≥ 10 yr. The strongest association occurred in women > 50 yr old and among those at low natural risk of breast cancer. The former finding is in keeping with recent concepts of possible divergent etiologies of pre- and postmenopausal breast cancer, and the latter suggests the hypothesis that high natural risk tends to mask the relatively small effects of hair dye exposure. (36 refs)

79-0711 Autoradiography of Deposition of Tobacco Smoke Particulate Matter in Isolated Perfused Rat Lung. (Eng) Bibby, M. C. (Postgraduate Sch. Studies in Medical and Surgical Sciences, Univ. Bradford, Bradford BD7 1DP, W. Yorkshire, England); Gilpin, C. J.; MacDonald, C. M.; Boardman, L. E. *Eur J Drug Metab Pharmacokin* 3(3): 141-145; 1978.

An isolated perfused rat lung system was used to study the deposition of tobacco smoke particulate material following inhalation of labeled mainstream smoke from standard flue-cured cigarettes. Radioactivity occurred throughout the lung but was concentrated within small bronchi. (12 refs)

79-0712 Cigarette Smoking and Bronchial Carcinoma: Dose and Time Relationships among Regular Smokers and Lifelong Non-Smokers. (Eng) Doll, R. (Radcliffe Infirmary, Univ. Oxford, Oxford, England); Peto, R. *J Epidemiol Commun Health* 32(4): 303-313; 1978.

In a 20-yr prospective study of the relationship between cigarette smoking and bronchial carcinoma in 34,440 British doctors, dose and time relationships were analyzed among regular smokers and lifelong nonsmokers. As is known, incidence

rates in the age range 40-79 are proportional to a power of duration of smoking, in excellent conformity with the predictions of the simple multistage model theory. To estimate this power, smoking duration was calculated by subtracting a chosen quantity (22.5 yr) from the age. Having done this, the best-fitting exponent was found to be 4.5 ± 0.3 ; ie, among cigarette smokers who started smoking at age 16-25 and who smoked ≤ 40 cigarettes/day, the annual lung cancer incidence in the age range 40-79 was $0.273 \times 10^{-12} \cdot (\text{cigarettes/day} + 6)^2 \times (\text{age} - 22.5)$ to the 4.5 power. The form of the dependence on dose in this relationship is subject not only to random error but also to serious systematic biases, which are discussed. However, there was certainly some statistically significant ($p < 0.01$) upward curvature of the dose-response relationship in the range 0-40 cigarettes/day, which is what might be expected if more than one of the stages (in the multistage genesis of bronchial carcinoma) was strongly affected by smoking. If a higher than linear dose-response relationship exists between dose per bronchial cell and age-specific risk per bronchial cell, this may help explain why bronchial carcinomas chiefly arise in the upper bronchi, as dilution effects might then protect the larger areas lower in the bronchial tree. (10 refs)

79-0713 The Chromatid Gap as a Folding Defect. Evidence from Mercaptoethanol and Caffeine Treatment (Meeting Abstract). (Eng) Brogger, A. (Genetics Lab., Norsk Hydro Inst. Cancer Res., Montebello, Oslo, Norway); Waksvik, H. *Clin Genet* 14(5): 282; 1978. (1 ref)

79-0714 Chromosomal Aberrations of Don Lung Cells of Chinese Hamster after Exposure to Vinblastine In Vitro. (Eng) Segawa, M. (Faculty Integrated Arts and Sciences, Hiroshima Univ., Hiroshima 730, Japan); Nadamitsu, S.; Kondo, K.; Yoshizaki, I. *Mutat Res* 66(1): 99-102; 1979.

Growing cultures of Chinese hamster (Don) lung cells were incubated with 0.0039, 0.0078, or 0.0156 $\mu\text{g/ml}$ vinblastine (VLB) for 2-32 hr, and the frequency of chromosome aberrations was determined. Colchicine (0.5 $\mu\text{g/ml}$) was added 2 hr before fixation. Chromosomes were stained with Giemsa, and 100 metaphase cells were examined for each VLB concentration. The number of lobulated nuclei at interphase increased gradually, beginning approx 2 hr after treatment. At all three concentrations, the numbers of chromosomal aberrations increased gradually up to 10 hr (when 28%, 44%, and 35% of metaphases contained aberrations at three increasing doses, respectively) and then decreased slightly. The mitotic index decreased steadily with increasing duration of treatment. The most common aberrations were gaps; chromatid and isochromatid breaks, rings, and chromatid exchanges plus other minor aberrations were also noted. Endoreduplicated chromosomes often contained multiple aberrations,

the incidence of which correlated with VLB concentration and duration of exposure. (15 refs)

79-0715 High-Performance Liquid Chromatography of Aflatoxins with Fluorescence Detection. (Eng)

Manabe, M. (Natl. Food Res. Inst., Ministry Agriculture and Forestry, Japan); Goto, T.; Matsuura, S. *Agric Biol Chem* 42(11): 2003-2007; 1978.

Studies were conducted to select various optimum conditions for the fluorometric determination of aflatoxin B₁, B₂, and G₂ by high-performance liquid chromatography using a 12 μ l flow cell. Good mutual separation of all four aflatoxins without quenching of their fluorescence was achieved using a silica gel column and a toluene-ethyl acetate-forming acid-methanol (89.0:7.5:2.0:1.5 v/v/v/v) solvent system. An increase in temperature from 20 to 35 C resulted in a 40% decrease in the fluorescence intensity of the aflatoxin B group, indicating the need for a relatively constant temperature when analyzing this group. The quantitative determinations of the four aflatoxins were linear in the range of 0.3-120 nanograms. Application of the method to samples of rice, corn, peanut meal, and mixed feed contaminated with aflatoxins showed that it was sensitive to levels as low as 10-20 ppb. (14 refs)

79-0716 A Method to Screen for Rubratoxin B and Other Mycotoxins in Corn. (Eng) Whidden, M. S. (Auburn Univ., Auburn, AL, 36830). *Diss Abstr Int B* 39(7): 3286B; 1979. (no refs)

79-0717 Mutagenicity and Antibacterial Activity of Mycotoxins Produced by *Penicillium islandicum* Sopp and *Penicillium rugulosum*. (Eng) Stark, A. A.

(Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Room 56-123, Cambridge, MA, 02139); Townsend, J. M.; Wogan, G. N.; Demain, A. L.; Manmade, A.; Ghosh, A. C. *J Environ Pathol Toxicol* 2(2): 313-324; 1978.

Twelve mycotoxins produced by *Penicillium islandicum* Sopp and *P. rugulosum* during solid-state fermentation on grains were purified and tested for mutagenicity and antibacterial activity in *Salmonella*/mammalian microsome assays. Lumiluteoskyrin, (+)rugulosin, rubroskyrin, and simatoxin induced mutations to 8-azaguanine resistance in suspensions of *Salmonella* strain TM677 (a histidine prototrophic revertant of strain TA1535 into which the ampicillin-resistance plasmid pKM101 was inserted), whereas (-)luteoskyrin, cyclochlorotine, iridoskyrin, pibasterol, chrysophanol, emodin, and skyrin were not mutagenic in this system. All *P. islandicum* mycotoxins except iridoskyrin, emodin, chrysophanol, and islandicin showed a concentration-dependent antibacterial activity. When tested with TM677 on plates, rubroskyrin and (+)rugulosin were antibacterial and mutagenic, simatoxin

in was mutagenic but only weakly antibacterial, and (-)luteoskyrin was antibacterial but not mutagenic. Purines and purine nucleosides protected TM677 cells from the inhibitory effects of 8-azaguanine. With a single exception, the mycotoxins did not induce histidine-independent revertants in *S. typhimurium* strains TA98 and TA100. A high concentration (130 μ g/reaction) of simatoxin had low mutagenic activity in suspensions of TA98. (20 refs)

79-0718 Dietary Protein Levels and Aflatoxin B₁ Metabolism in Rainbow Trout (*Salmo Gairdneri*). (Eng) Stott, W. T. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR, 97331); Sinnhuber, R. O. *J Environ Pathol Toxicol* 2(2): 379-388; 1978.

The influence of three levels of dietary fish protein concentrate (FPC) on the in vitro activities of male rainbow trout hepatic enzyme systems that may be involved in the metabolism of aflatoxin B₁ (AFB) was studied. The size of the livers of fish given 52% and 62% FPC diets were increased compared with those of fish given a 32% FPC diet. Aldrin epoxidase was decreased twofold and 40%, respectively, in fish fed 52% and 62% FPC diets relative to the level in fish fed the 32% FPC diet. The activities of hepatic glutathione-S-epoxide transferase (20%), epoxide hydrolase (15%) and cytochrome c reductase (13%) also decreased with increasing dietary FPC. In contrast, a direct correlation was observed between increased FPC intake and cytochrome P-450 level and aflatoxicol production, with increases of 14% and 41%, respectively. The data provide evidence that the level of dietary protein can influence the in vitro activities of rainbow trout hepatic xenobiotic metabolizing enzyme systems. (54 refs)

79-0719 Distribution of (¹⁴C)-Labeled Aflatoxin B₁ in Mice. (Eng) Arora, R. G. (Dept. Pathology, Coll. Veterinary Medicine, Swedish Univ. Agricultural Sciences, S-750 07 Uppsala, Sweden); Appelgren, L. E.; Bergman, A. *Acta Pharmacol Toxicol (Kbh)* 43(4): 273-279; 1978.

The distribution of ¹⁴C-labeled aflatoxin B₁ (AFB) was studied in CBA mice by whole-body autoradiography. Six males and 2 nonpregnant and 2 pregnant females were given 3.13 μ Ci (7.8 μ g) AFB iv. The male mice were sacrificed 5, 20, and 60 min, 4 and 24 hr, and 4 days after injection. The nonpregnant females were sacrificed 5 and 60 min, the pregnant mice 20 min and 4 hr after injection, which in the latter was on gestation day 17. In addition to localization of AFB and/or its metabolites in the liver, bile, kidney, lung and urine, an uptake of ¹⁴C was also seen in the pigment of the Harderian gland and in the eye. A pronounced uptake was also seen in the pigment layer of the fetal eye and in the nasal mucosa but not in the fetal liver. A specific pattern of activity was seen in the adult kidney: there was a higher uptake of ¹⁴C in the medulla, leaving the cortex almost void of radioac-

tivity. This might indicate that the most vulnerable site of action of AFB is in the kidney. The significance of the specific kidney uptake and the pigment affinity of AFB are under further investigation. (14 refs)

- 79-0720 Variation in the Incidence of "Spontaneous" Tumours (Letter to Editor).** (Eng) Schoental, R. (Dept. Pathology, Royal Veterinary Coll., Univ. London, London, England). *Br J Cancer* 39(1): 101; 1978.

Carcinogenic mycotoxins (eg, T-2 toxin, aflatoxins) that can contaminate cereals harvested during wet and cold weather may have caused the drastic changes in the incidence of "spontaneous" tumors in laboratory animals at various institutes or at the same institute at different times. To avoid these misleading complications, the absence of mycotoxins from every batch of diet given to the animals must be ensured. (5 refs)

- 79-0721 Inhibition of Hepatic Toxicities from Polybrominated Biphenyls and Aflatoxin B₁ in Rats Fed Cauliflower.** (Eng) Stoewsand, G. S. (Dept. Food Service and Technology, Cornell Univ., Geneva, NY, 14456); Babish, J. B.; Wimberly, H. C. *J Environ Pathol Toxicol* 2(2): 399-406; 1978.

The effects of dietary cauliflower on the hepatotoxicity of polybrominated biphenyls (PBB's) and aflatoxin B₁ (AFB) were studied in weanling male Sprague-Dawley rats. In the first experiment, rats were fed a purified basal diet or a 25% freeze-dried cauliflower leaf diet for 3 wk, followed by 0, 1, or 50 ppm PBB in their respective diets for 20 days. In the second experiment, rats were fed the basal diet or a 20% cauliflower head diet plus 2 ppm AFB for 26 wk and then the basal diet for 15 wk. The 25% cauliflower leaf diet produced increased liver wts, especially in rats fed 50 ppm PBB. Hepatic aryl hydrocarbon hydroxylase (AHH) did not increase with the cauliflower diets but only with the highest level of dietary PBB. However, hepatic aminopyrene N-demethylase, p-nitroanisole O-demethylase, and cytochrome P-450 increased in a dose-dependent fashion in rats given cauliflower and PBB. (A preliminary study showed that freeze-dried cauliflower heads produced a similar pattern of hepatic mixed-function oxidase induction.) The apparent K_m of AHH in the liver, intestine, and kidney decreased, the V_{max} of intestinal AHH increased, and the V_{max} of renal AHH decreased in rats given cauliflower. Total lipids decreased in animals given cauliflower plus 50 ppm PBB. After 41 wk, rats given the basal diet and AFB died and showed Grades I and II liver adenomas, plus metastasis and severe internal hemorrhaging. All rats given cauliflower plus AFB lived, but they did exhibit lowered body wts and small, localized Grades I and II hepatic adenomas. Thus, microsomal enzyme induction, especially in liver and intestine, affords a detoxification mechanism for PBB and AFB in animals given dietary cauliflower. (25 refs)

- 79-0722 Alterations of Brain and Intestine Serotonin Levels in Hamsters Pretreated with Dietary Aflatoxin.** (Eng) Weekley, L. B. (Dept. Biology, Virginia Commonwealth Univ., Richmond, VA, 23284); Morgan, T. D.; Rea, F. W.; Kimbrough, T. D.; Llewellyn, G. C. *Cancer Lett* 5(2): 75-80; 1978.

The effects of dietary mixed-aflatoxin (AFT) pretreatment on serotonin levels were studied in male Syrian hamsters. Groups of six animals received either Purina laboratory meal (control diet) or a similar diet containing 30.3 ppm AFT (13.8 ppm AFB₁, 0.4 ppm AFB₂, 15.6 ppm AFG₁, and 0.5 ppm AFG₂) for 45 days, followed by the control diet for 123 days (recovery period). The animals were then sacrificed. Serotonin was decreased significantly in the duodenum of experimental animals, and although it was also decreased in brain, this difference was not significant. 5-Hydroxyindoleacetic acid was insignificantly elevated in AFT-treated animals. The livers of these animals displayed histopathological changes, including megalocytes, bile duct hyperplasia, and nuclear inclusion bodies. No gross tumors were seen in livers or intestines of any animal. Experimental animals experienced a net wt loss of 13.07% during the 45-day treatment period (vs control gains of 52.94%) and a rapid increase in the recovery period (87.95% vs 16.46%). However, the experimental animals never attained a body wt equal to that of controls. Following AFT treatment in the male hamster, responses to body wt, liver pathology, and serotonin appear to become "permanent" at differential levels. (21 refs)

- 79-0723 Morphology of Bacon and Its Possible Role in Formation of Nitrosamines.** (Eng) Cassens, R. G. (Muscle Biology Lab., Coll. Agricultural and Life Sciences, Univ. Wisconsin, Madison, WI, 53706); Ito, T.; Lee, M. *J Food Sci* 44(1): 306-307; 1978.

Morphologically, bacon is composed of regions of skeletal muscle or lipid-filled cells (adipocytes) characterized by a typical mammalian cell wall that encloses a single large lipid globule (LG). A thin layer of cytoplasmic protein, which contains cell organelles, is interposed between the cell wall and the LG. The interface between the nonpolar LG and the cytoplasmic and connective tissue proteins may present a unique site for reaction with nitrite-containing brine to form nitrosamines. (14 refs)

- 79-0724 The Dose-dependent Fate of 1,4-Dioxane in Rats.** (Eng) Young, J. D. (Toxicology Res. Lab., Dow Chemical Co., Midland, MI, 48640); Braun, W. H.; Gehring, P. J. *J Environ Pathol Toxicol* 2(2): 263-282; 1978.

A pharmacokinetic study was conducted to determine the dose-dependent fate of dioxane (given po, iv, and by inhalation) at doses identical to those given in toxic

cological studies in male Sprague-Dawley rats. The plasma concentration-time curves at low doses by each route were linear, with half-life values of about 1 hr. As the dose was increased above 10 mg/kg, the plasma clearance rate decreased, the fraction of the dose excreted in the urine as β -hydroxyethoxyacetic acid (HEAA) decreased, and the fraction of the dose excreted as dioxane in the urine and expired breath increased. The data could be described by a one-compartment open system model with parallel first-order (urinary and pulmonary excretion) and Michaelis-Menten (metabolism) type elimination kinetics. At saturation, the max velocity of the metabolism of dioxane to HEAA was about 18 mg/kg/hr. Multiple daily po doses of 1,000 mg/kg, but not 10 mg/kg, were excreted more rapidly than equivalent single doses, indicating that at high daily doses dioxane induced its own metabolism. The correlation of the dose-dependent fate of dioxane with the results of toxicological studies in rats supports the conclusion that there is an apparent threshold for the toxic effects of dioxane that coincides with saturation of the metabolic pathway for its detoxification. (26 refs)

79-0725 Residue Determination of Hydrazine in Water by Derivatization and Gas Chromatography.

(Eng) Selim, S. (Div. Chemistry and Physics, Food and Drug Admin., 200 C St., S.W., Washington, DC, 20204); Warner, C. R. *J Chromatogr* 166(12): 507-511; 1978.

A method is described in which the hydrazine residue in water is determined by converting hydrazine to acetone azine, extracting the acetone azine with methylene chloride, and detecting the acetone azine by gas chromatography using a nitrogen/phosphorus detector. The limit of detection is 0.1 ppb, and the recoveries averaged 92% for water fortified with 0.1-10 ppb hydrazine. The derivatization of trace hydrazine levels with a large excess of acetone proceeded quantitatively in 53 min in a methanolic system and in < 2 min in an aqueous system. (18 refs)

79-0726 Mechanism of Methylation of DNA Bases by Symmetric Dimethylhydrazine.

(Rus) Likhachev, A. Ia. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Petrov, A. S.; P'rvanova, L. G.; Pozharisskii, K. M. *Biull Eksp Biol Med* 86(12): 679-681; 1978.

The ability of disulfiram (DS) to block the formation of carbonium ion was employed for the analysis of the mechanism of methylation of DNA by 1,2-dimethylhydrazine (DMH). Random-bred rats received DS in sunflower oil (5 g/kg/d, po, for 8 days); 4 hr after the last DS administration rats were inoculated sc with ^3H -DMH (21 mg/kg) and 9 hr later were sacrificed. DNA specimens, extracted from the large intestine and the liver, were fractionated chromatographically. DNA from both intestine and liver lacked alkylated purines, but

in rats treated with DMH alone, the O⁶-methylguanine level in hepatic DNA was two times greater than in intestinal DNA. These findings confirm the hypothesis that the carcinogenic effect of alkylating agents is based upon the formation of O⁶-methylguanine. (14 refs)

79-0727 Intestinal Transit Time as an Important Factor in the Pathogenesis of Dimethylhydrazine-induced Rat Colon Cancer.

(Eng) Baker, A. R. (Surgery Branch, NCI, NIH, Bethesda, MD, 20014); Ward, J. M.; Simon, R. M.; Stinson, S. F.; Devereux, D. F. *Surg Forum* 29: 491-492; 1978.

Male Fischer 344 rats were given one of three rations ad libitum and weekly sc injections of dimethylhydrazine (DMH: 20 mg/kg). Rats fed the bulk-free elemental liquid ration had about a twofold prolongation in their intestinal transit time and, at 20 wk, developed larger and greater numbers of colon tumors than did rats fed solid, bulk-containing diets. Thus, intestinal transit time is important in the pathogenesis of DMH-induced rat colon tumors. (1 ref)

79-0728 1,2-Dimethylhydrazine-induced Methylation of DNA Bases in Various Rat Organs and the Effect of Pretreatment with Disulfiram.

(Eng) Swenberg, J. A. (Chemical Industry Inst. Toxicology, P.O. Box 12137, Research Triangle Park, NC, 27709); Cooper, H. K.; Bucheler, J.; Kleihues, P. *Cancer Res* 39(2, Part 1): 465-467; 1979.

The formation and persistence of methylated DNA bases following in vivo administration of ^{14}C -1,2-dimethylhydrazine (^{14}C -SDMH) with or without disulfiram (DS) pretreatment was studied in female BD-IX rats. The pretreatment group received 5 mg/g DS in their diet beginning 8 days prior to SDMH and continuing until sacrifice. All animals were inoculated sc with a single dose of 4 or 20 mg/kg SDMH and sacrificed 1.5 hr to 7 days later. The DNA of various organs was analyzed for the presence of methylated purines. The concentration of O⁶-methylguanine increased rapidly during the first 6 hr after SDMH administration and peaked at 12 hr, with the highest levels of N-7- and O⁶-methylguanine being detected in liver, followed by colon, ileum, and kidney. No purine alkylation was detected in stomach or brain. Removal of O⁶-methylguanine was most rapid in ileum and liver and least rapid in colon, the principal target for carcinogenesis. Rats receiving 20 mg/kg SDMH produced approx 10 times the amount of colonic O⁶-methylguanine produced in 4-mg/kg-treated rats. This is twice the level expected from a linear dose response. DS pretreatment reduced DNA alkylation to < 1% of that detected in rats receiving SDMH alone. The combination of persistent O⁶-methylguanine and cell replication, ie, DNA damage and repair, in the colon may provide an explanation for the organ-specific carcinogenicity of SDMH. (20 refs)

79-0729 Failure of Bran to Protect Against Experimental Colon Cancer in Rats. (Eng) Cruse, J. P. (Surgical Unit, University Coll. Hospital Medical Sch., Rayne Inst., University St., London WC1E 6FF, England); Lewin, M. R.; Clark, C. G. *Lancet* 2(8103): 1278-1280; 1978.

The effect of varying the fiber content of a diet on the induction of colon cancer by 1,2-dimethylhydrazine (DMH) was examined in a long-term study using 60 female Wistar rats. The rats were fed the same formula solid diet but given three different amounts of dietary fiber: 20 were given 4.8% wt/wt crude fiber, 20 were given 20% wt/wt bran, and 20 received no fiber. Half of the animals in each group were given DMH (40 mg/kg/wk sc) for 13 wk. All carcinogen-treated rats died during the 1-yr study, and all deaths were attributable to histologically proved adenocarcinoma of the colon. The incidence of colonic carcinoma in each DMH-treated fiber group was therefore 100%. These findings do not support the hypothesis that a high-bran diet will protect against chemically induced experimental colon cancer. (20 refs)

79-0730 Co-carcinogenic Effects of Dietary Cholesterol in Experimental Colon Cancer. (Eng) Cruse, J. P. (Surgical Unit, Univ. Coll. Hosp. Medical Sch., University St., London WC1, England); Lewin, M. R.; Ferulano, G. P.; Clark, C. G. *Nature* 276(5690): 822-825; 1978.

The ability of dietary cholesterol to promote the induction of colon cancer by dimethylhydrazine (DMH) was studied in female Wistar rats. DMH-treated (40 mg/kg/wk, sc, for 13 wk) animals fed Vivonex, a cholesterol-free, chemically defined liquid diet, showed a highly significant increase in both time to tumor presentation ($p < 0.001$) and survival ($p = 0.001$) when compared with carcinogen-injected controls fed a standard diet. This suggested that Vivonex protected against DMH carcinogenesis. The addition of cholesterol to Vivonex significantly reduced both the time to tumor presentation ($p < 0.001$) and survival ($p = 0.008$) and increased the incidence of metastases ($p = 0.028$). Sixty-seven percent of the animals fed Vivonex plus cholesterol had abdominal carcinomas at necropsy. The results suggested that cholesterol is a potent dietary cocarcinogen. (34 refs)

79-0731 Pathological Features of the Colonic Tumours Induced in Rats by the Administration of 1,2-Dimethylhydrazine. (Eng) Sunter, J. P. (Dept. Pathology, Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, England); Appleton, D. R.; Wright, N. A.; Watson, A. J. *Virchows Arch [Cell Pathol]* 29(3): 211-223; 1978.

The frequency, distribution, and histopathology of colonic tumors induced in female Wistar Porton rats by 1,2-dimethylhydrazine (DMH, 15 mg/kg/wk sc for up to 30 wk) were studied. The incidence of colonic tumors was 92% in rats sacrificed at 24 wk, 89% in those sacrificed at 27 and 28 wk,

and 100% in those sacrificed at 30 wk. All tumors were of epithelial origin. Twenty-six percent of the tumors were benign adenomas, which arose in the distal three-fifths of the large bowel. Sixteen percent of the tumors were locally invasive, well-differentiated adenocarcinomas, which also arose in the distal three-fifths of the bowel. Well- and moderately well-differentiated adenocarcinomas showing greater invasion of the bowel wall were seen throughout the entire colon, especially the middle third, and they comprised 40% of the tumors. The largest tumors were poorly differentiated mucin-secreting adenocarcinomas that frequently invaded the full thickness of the bowel. They were largely confined to the proximal third of the colon and comprised 18% of all tumors. The proximal one-tenth of the colon was tumor-free. No completely anaplastic tumors were seen. The mean number of tumors per animal increased with duration of DMH treatment. Recently, demonstrated regional differences in the kinetic organization of normal colonic mucosa may influence the nature of the neoplastic change induced by DMH, thus accounting for the differences in tumor distribution. (14 refs)

79-0732 Tumours of the Anal Region Induced in Mice By 1,2-Dimethylhydrazine. (Eng) Turusov, V. S. (Cancer Res. Center, USSR Acad. Medical Sciences, Kashiirskoye Shosse 6, Moscow, 115478, USSR). *Cancer Lett* 5(2): 97-102; 1978.

When female CBA mice were treated with 1,2-dimethylhydrazine (8 mg/kg for 40 wk, sc), they developed, in addition to tumors of the uterus, colon, liver, and other sites, a high incidence of benign and malignant tumors in the anal region. There were 28 in all, 12 perianal gland tumors, 12 squamous carcinomas, and 4 papillomas and keratoacanthomas. The first five perianal tumors were found 22-30 wk after the start of treatment, and they appeared as small intracutaneous or sc nodules undergoing ulceration. The structure of these lesions was similar to that of the perianal sebaceous glands, and they were surrounded by a fibrous capsule. They largely retained their organoid structure; ie, a squamous component originating from the ducts and a sebaceous component. In advanced stages, one of these components (usually the squamous) dominated. Most of these tumors were well demarcated from the surrounding tissues. Morphologically, they could be diagnosed as adenomas, adenoacanthomas, or carcinomas. In at least 4/12 squamous cell carcinomas, a perianal gland origin was indicated by the presence of sebocytes within the tumors. The papillomas or keratoacanthomas were found at the junction of the cylindrical and squamous epithelium of the anus. This study showed that many DMH-induced anal tumors do not originate primarily from the epidermis but rather from the perianal glands located deep in the subcutis. (7 refs)

79-0733 Dietary Fibre and Chemically Induced Bowel Tumours (Letter to Editor). (Eng) Brown, S. M.

(Biometry Branch, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Falk, H. L. *Lancet* 2(8102): 1252; 1978.

A previous experiment demonstrating a dose-response influence of dietary fiber in protecting rats against the carcinogenic effects (bowel tumors) of dimethylhydrazine (DMH) could have been better designed. The protein and fat levels in the diets should have been held constant, the number of animals should have been larger, and the dose of DMH should have been varied. In addition, two diets used, which represented the extremes of fiber content, were growth inhibitory at a toxic level. (5 refs)

79-0734 Experimental Colonic Tumours in the Rat. III. Induction Time, Distribution and Appearance of Induced Tumours. (Eng) Lindstrom, C. G. (Res. Labs., Depts. Diagnostic Radiology and Pathology, Malmo Allmanna Sjukhus, S-214 01 Malmo, Sweden); Rosengren, J. E.; Ekberg, O. *Acta Radiol [Diagn] (Stockh)* 19(5): 799-816; 1978.

The induction time, distribution, and appearance of colonic tumors induced in Wistar/Furth and BD rats by 1,2-dimethylhydrazine (DMN, 20 mg 3x/wk ip for 11 wk, 15-25 mg/wk sc for 15 wk, or 15-45 mg/kg/wk sc for 4-12 wk) or N-methyl-N'-nitro-N-nitrosoguanidine (MNNG, 0.5 ml of a 0.25% soln 1x/wk for 11-16 wk intrarectally) were studied. A total of 214 malignant adenomatous colonic tumors developed in 114/189 drug-treated rats; 18 of these tumors were overlooked or misinterpreted at radiography. Induction time was shorter with DMH given sc in a small dose than with DMH given ip in a higher dose. DMH-treated rats most often developed one to two tumors, and adenocarcinomas of well, moderately, and poorly differentiated types occurred; 60% of these tumors appeared within 9 mo. MNNG-treated rats often developed more than three tumors, and the adenocarcinomas were mainly well differentiated; 78% of these tumors appeared after 9 mo. MNNG-induced tumors did not metastasize and did not occur outside the large bowel, whereas DMH-induced tumors metastasized ip and to lymph nodes in 21 (17.5%) cases and appeared outside the large bowel (small bowel, kidney, liver-biliary tract) in 64 cases. The distribution and occurrence of carcinomas and adenomas suggested that they are generated by the same biologic mechanism acting on the epithelium. There seemed to be a relationship between the various types of mucosa in the colon and rectum and the carcinomas developing from them. (24 refs)

79-0735 The Degradation of Different Forms of Cytochrome P-450 In Vivo by Fluroxene and Allyl-isopropylacetamide. (Eng) Bradshaw, J. J. (Dept. Medical Biochemistry, Univ. Cape Town Medical Sch., Cape Town, South Africa); Ziman, M. R.; Ivanetich, K. M. *Biochem Biophys Res Commun* 85(3): 859-866; 1978.

Fluroxene (FL) and allylisopropylacetamide (AIA) decreased hepatic cytochrome (cyt) P-450 levels in control rats and rats pretreated with phenobarbital (PB) or 3-methylcholanthrene (3-MC) and equivalently decreased microsomal heme, aniline binding, and p-nitroanisole demethylase. FL and AIA degraded multiple forms of cyt P-450 following PB induction, but degraded in the greatest amounts the form(s) of P-450 induced by PB. After 3-MC induction, FL preferentially degraded cyt P-448, but AIA remained relatively specific for the form(s) of P-450 induced by PB. (23 refs)

79-0736 Chemical Carcinogen FANFT Induces an Increase in Intramembrane Particle Numerical Densities in Urinary Bladder Epithelium (Meeting Abstract). (Eng) Pauli, B. U. (Dept. Pathology, Rush Medical Coll., Chicago, IL); Friedell, G.; Weinstein, R. S. *J Cell Biol* 79(2, part 2): 227a; 1978. (1 ref)

79-0737 Topography and Numerical Densities of Intramembrane Particles in Chemical Carcinogen-induced Urinary Bladder Carcinomas in Fischer Rats. (Eng) Pauli, B. U. (Dept. Pathology, Rush-Presbyterian-St. Luke's Medical Center, 1753 W. Congress Parkway, Chicago, IL, 60612); Friedell, G. H.; Weinstein, R. S. *Lab Invest* 39(6): 565-573; 1978.

Intramembrane particle (IMP) numerical densities and topographic distributions were compared in chemically induced noninvasive and invasive bladder tumors. Moderately well differentiated papillary transitional cell carcinomas were produced by feeding weanling male Fischer rats N-(4-(5-nitro-2-furyl)-2-thiazolyl)formamide (FANFT) at a dose of 0.2% of their diet for 26 wk. Tumors developing by 26 wk were small and noninvasive. At 61 wk, the tumors were large and invasive. The numbers of IMP on the protoplasmic (P) faces (IMPP) in both noninvasive and invasive urothelial tumors were significantly increased over control values ($p < 0.01$). The density of IMP particles on the external faces in normal rat urothelium and in noninvasive and invasive FANFT-induced bladder tumors were not significantly different. Using several statistical methods that test IMP topography vis-a-vis the Poisson (random) hypothesis, it was demonstrated that IMP are mathematically randomly distributed in the large majority of plasma membranes of cells in normal rat bladder epithelium and in invasive FANFT-induced tumors. In noninvasive carcinomas, IMP were in a lattice-like arrangement in half of the tumor cells and randomly distributed in the remainder. The results document that, in the course of malignant transformation of the rat urinary bladder epithelium, numerical densities and topographic distributions of IMPP are altered. Such alterations may be related to intrinsic or extrinsic stimuli that introduce changes in the interactions of the plasma membrane with membrane-associated constituents. The possibility also exists that changes in IMPP numerical densities and topographic

distributions with neoplastic transformation may represent epiphenomena, at least in FANFT-induced urinary bladder carcinomas in Fischer rats. (63 refs)

- 79-0738 Effect of Azathioprine and OK-432 on Urinary Bladder Carcinogenesis in Rats.** (Eng) Cohen, S. M. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Fukushima, S.; Tsuda, H.; Murasaki, G.; Ito, N. *Gann* 69(6): 773-779; 1978.

The effect of azathioprine (ATP) and OK-432 on bladder carcinogenesis in rats was evaluated using the carcinogens N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN) and N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT). OK-432 is a streptococcal preparation that enhances cellular immune and reticuloendothelial responsiveness to tumors in animals and, in preliminary studies, in humans. Male Fischer rats were administered 0.01% BBN in the drinking water or 0.2% FANFT in the diet for 8 wk, alone, or before, during, or after 8 wk of 0.02% ATP in the diet. Some rats were given ATP alone, others a control diet. In another experiment, the rats were given 8 wk of BBN alone or before, during, or after 8 wk of OK-432 (5KE 2x/wk, sc). One group of rats received BBN for 8 wk followed by OK-432 for 32 wk. ATP did not affect FANFT bladder carcinogenesis in any treatment. When ATP was fed simultaneously with BBN, however, there was a significant increase in the incidence of bladder tumors, although ATP had no effect on tumor incidence when it was administered before or after BBN. Short-term administration of OK-432 before, during, or after BBN did not affect bladder carcinogenesis, but if OK-432 was begun after BBN and continued until the end of the experiment, the incidence of BBN-induced bladder tumors was significantly reduced. No bladder lesions were observed in control rats or in rats receiving ATP or OK-432 alone. (27 refs)

- 79-0739 The Effects of Dietary Protein, Fat and 2-Acetylaminofluorene on the Microsomal Activity Levels of Liver from BALB/c Mice.** (Eng) Lazear, E. J. (Dept. Health, Education and Welfare, Natl. Center Toxicological Res., Food and Drug Admin., Jefferson, AR, 72079); Louie, S. C.; Shaddock, J. G.; Barren, P. R.; Norvell, M. *Toxicol Lett* 2(6): 345-350; 1978.

The effects of dietary protein (12% or 24% of the diet), fat (4% or 24% of the diet, as corn oil), and 2-acetylaminofluorene (2-AAF, 0 or 500 ppm) on the biological activity of the hepatic microsomal system were studied using weanling female BALB/c mice and the Ames *Salmonella typhimurium* assay system. The experimental diets were fed continuously for 77 wk. In the Ames assay, liver S-9 fractions from animals on the high-fat diets had significantly lower activity levels than the fractions from animals on the low-fat diets. Protein concentration had no significant effect, but 2-AAF had a

strong inducing effect, especially in the high-fat diet groups. Thus, the metabolic functions of laboratory animals can be altered drastically by modifications in the diet. Nearly all of the animals given 2-AAF had liver nodules, and numerous sc growths were observed in the inguinal areas and the regions near the mammary glands. (7 refs)

- 79-0740 Effects of Selenium and Retinoic Acid on the Metabolism of N-Acetylaminofluorene and N-Hydroxyacetylaminofluorene.** (Eng) Daoud, A. H. (Dept. Biochemistry, Univ. Texas System Cancer Center, M.D. Anderson Hosp. Tumor Inst., Houston, TX, 77030); Griffin, A. C. *Cancer Lett* 5(4): 231-237; 1978.

The effect of selenium (4 ppm in drinking water for 3 days) or retinoic acid (RA: 0.25% wt/wt in the diet for 3 days) on enzymes involved in the metabolism of acetylaminofluorene-9-¹⁴C and N-hydroxyacetylaminofluorene-9-¹⁴C (AAF and OH-AAF: each, 17 mg/kg ip) and the binding of these two compounds to liver nucleic acids was studied in male Sprague-Dawley rats. Se and RA enhanced the liver activity of OH-AAF glucuronyl transferase, decreased the activity of sulfotransferase, and had no effect on AAF deacylase. Se-treated rats showed lower radioactivity in most liver fractions than controls after AAF and OH-AAF administration. The livers of rats given Se and AAF or OH-AAF did not differ markedly from control rats with respect to ethyl acetate- and ether-extractable components. However, the level of these components was 20 times lower in AAF-treated livers than in OH-AAF-treated livers. Se inhibited the binding of OH-AAF to liver DNA and transfer RNA by 30% and 20%, respectively, but had a negligible effect on the binding of AAF to liver DNA. The data support the hypothesis that retinoids and Se slow down or reduce chemical carcinogenesis by altering the metabolism and detoxification of cancer inducing agents. (14 refs)

- 79-0741 2-Acetylaminofluorene-induced Unscheduled DNA Synthesis in Hepatocytes Isolated from 3-Methylcholanthrene Treated Rats.** (Eng) Casciano, D. A. (Div. Mutagenesis Res., HFT-120, Natl. Center Toxicological Res., Jefferson, AR, 72079); Farr, J. A.; Oldham, J. W.; Cave, M. D. *Cancer Lett* 5(3): 173-178; 1978.

The induction of unscheduled DNA synthesis (UDS) by 2-acetylaminofluorene (AAF) and N-hydroxy-2-acetylaminofluorene (N-OH-AAF) in hepatocytes isolated from untreated or 3-methylcholanthrene-induced (3-MC: 100 mg/kg ip 24 hr before hepatocyte isolation) Sprague-Dawley rats was studied autoradiographically. A dose-dependent increase in UDS was noted after N-OH-AAF treatment even without 3-MC induction, suggesting that hepatic cells from uninduced animals retained sufficient enzymatic capacity to metabolically activate N-OH-AAF. All doses of AAF increased the level of

³H-thymidine incorporation above that of controls, but the increases were not dose-dependent. This suggests that cellular levels of N-hydroxylating enzymes were inadequate. Upon 3-MC treatment, however, the increase in AAF-induced UDS was dose-dependent. In both cases, 3-MC treatment not only increased the amount of UDS/cell, but also the percentage of cells induced to repair their DNA. These results confirm the observation that induction of UDS in primary rat hepatocyte cultures can be used to detect potential carcinogens, and they suggest that the sensitivity of the system may be enhanced (at least for aromatic amines) by 3-MC treatment prior to hepatocyte isolation. 79-0742 The Binding of ¹⁴C-Labelled Acetylaminofluorene to Nuclear Proteins and DNA. (Eng) Gro-now, M. (Cancer Res. Unit, Univ. York Heslington, York YO1 5DD, England); Lincoln, J. C. *Cancer Lett* 5(5): 269-275; 1978.

A study was made of the covalent binding of acetylaminofluorene (AAF) to liver nuclear protein fractions and DNA of male Wistar rats given two doses of ¹⁴C-labeled carcinogen (100 μ Ci, ip) 24 hr apart beginning 48 hr or 2 wk before sacrifice. Livers were removed immediately, nuclei were isolated, and most of the non-histone proteins (NHP) were removed by extraction with 8 M urea. After 48 hr, 80.9% of the AAF was bound to the urea extracted NHP, which also had the highest specific activity. Relatively small amounts were bound to histones (9.9%), residual proteins (5.9%), and DNA (3.3%). After 2 wk the label was redistributed, with more being present in histone and residual protein fractions, but again only a small amount of carcinogen was bound to DNA (0.23%). Pretreatment of rats with phenobarbital (PB: 1 mg/ml) or sodium sulfate (10 mg/ml) in drinking water for 10 days prior to AAF administration reduction binding to all fractions, with PB having a stronger effect. Contrary to expectation, PB did not produce higher binding to DNA. In fact, it reduced the specific activity of the DNA. Isoelectric focusing analysis of the NHP in polyacrylamide gels showed a complex binding pattern, with 14-16 ¹⁴C peaks of differing pI's containing the bulk of the bound carcinogen and no one component being labeled predominantly. The histone fraction was analyzed in a slab gel electrophoresis system. Only 23.5%-26% of the labeled carcinogen was recovered, and it was evenly spread out among the five histone components. These results indicate that although DNA appears to be the critical target in chemical carcinogenesis, the role of the various NHP species in the control of gene expression cannot be neglected. 79-0743 The Use of the D-T Diaphorase for the Detection of Foci of Early Neoplastic Transformation in Rat Liver. (Eng) Schor, N. A. (Dept. Pathology, Tulane Univ. Sch. Medicine, New Orleans, LA, 70112); Ogawa, K.; Lee, G.; Farber, E. *Cancer Lett* 5(3): 167-171; 1978.

Preneoplastic foci and hyperplastic nodules induced in rat liver by dietary acetylaminofluorene were analyzed for D-T diaphorase and glucose-6-phosphate dehydrogenase activity. The former enzyme was increased six times and the latter four times in the hyperplastic nodules. Histochemical staining techniques showed the localization of the diaphorase to be exclusively in the preneoplastic foci and in the liver nodules. These findings suggest that (1) neoplastic cells undergo at least two phenotypic changes, ie, the changes in the activity of these two enzymes in the early stages of carcinogenesis; (2) that D-T diaphorase may be useful for the quantitation of carcinogenicity in the liver; and (3) that D-T diaphorase may participate in the resistance of precancerous cells to the necrogenic action of chemical toxins. 79-0744 Biochemical Basis for the Resistance of Guinea Pigs to Carcinogenesis by 2-Acetylaminofluorene. (Eng) Kawajiri, K. (Biochemistry Div., Saitama Cancer Center Res. Inst., Ina-machi, Kitaadachi-gun, Saitama-362, Japan); Yonekawa, H.; Hara, E.; Tagashira, Y. *Biochem Biophys Res Commun* 85(3): 959-965; 1978.

The resistance of guinea pigs to 2-acetylaminofluorene (AAF)-induced carcinogenesis was investigated by examining the induction of cytochrome P-448 by 3-methylcholanthrene (MC) and the binding of AAF to the DNA in isolated guinea pig nuclei. Cytochrome P-448 and aryl hydrocarbon hydroxylase were not induced in either the microsomes or nuclei of guinea pigs by MC. MC caused only a 2-fold increase in the binding of AAF to DNA in guinea pig nuclei, but it caused a 17-fold increase in the binding to DNA in rat nuclei. The binding of N-hydroxy-2-acetylaminofluorene (N-OH-AAF), a proximate form of AAF, to DNA in nuclei of rats and guinea pigs was identical. It is concluded that there is a good correlation between the low inducibility of cytochrome P-448 and the low binding of AAF to DNA. The results indicate that guinea pigs are resistant to tumor induction of AAF through their inability to carry out the first step of AAF activation. (19 refs)

79-0745 Damage of Proliferating Lymphoid Cell Deoxyribonucleic Acid by Methyl Methanesulfonate and N-Acetoxy-2-acetylaminofluorene. (Eng) Warren, J. R. (Dept. Pathology, Northwestern Univ. Medical Sch., Chicago, IL, 60611). *Cancer Lett* 5(5): 253-260; 1978.

A method was developed for rapidly measuring carcinogen-induced damage to proliferating lymphocyte DNA by following changes in the rates of both DNA replicative and repair synthesis. DNA replicative synthesis by splenic lymphoid cells cultured from C57BL/6J mice and stimulated to proliferate with concanavalin A (Con A: 1.0 μ g/ml) was strongly suppressed during a short incubation (10-60 min) of the cells in medium containing methyl methanesulfonate (MMS: 0.2-0.8 mM) or N-acetoxy-2-acetylaminofluorene

(N-acetoxy-AAF: 0.005-0.01 mM). Carcinogen-treated lymphoid cells failed to recover stimulated levels of replicative synthesis after incubation for up to 3 hr in fresh medium without carcinogen. In contrast, spleen cells treated with hydroxyurea (HU), a metabolic inhibitor of DNA replication, fully recovered their ability for replicative synthesis when placed in fresh medium without added HU. In addition, the inhibition of replicative synthesis by the carcinogens was accompanied by marked stimulation of DNA repair synthesis. These results indicate that the rapid screening of carcinogenic and potentially carcinogenic chemicals for DNA-damaging properties should be possible by concomitant measurement of replicative and repair synthesis of DNA in *in vitro* cultures of proliferating lymphocytes treated with the test chemical. (20 refs)

79-0746 Inhibition of DNA-Repair and DNA-Synthesis by Harman in Human Alveolar Tumor Cells.

(Eng) Remsen, J. F. (Dept. Biochemistry and Molecular Biology, Univ. Florida, Box J245, JHMHC, Gainesville, FL, 32610); Cerutti, P. A. *Biochem Biophys Res Commun* 86(1): 124-129; 1979.

The effect of harman (HM), a tryptophan pyrolysis product, on colony-forming ability, DNA synthesis, and DNA repair was investigated in A549 human alveolar tumor cells. When A549 cells were treated for 48 hr with 25-200 μ M of HM, colony-forming ability decreased with increasing concentration. In addition, the size of the colonies was reduced at 200 μ M, indicating a significant increase in generation time. When A549 cells were prelabeled in their DNA with 14 C-thymidine, treated with HM for 10 min, and then pulsed for 15 min with 3 H-thymidine in the presence of HM, DNA synthesis capacity decreased to 29% of control values at 200 μ M HM. Since only 10 min preincubation with HM was required for inhibition of DNA synthesis, HM probably exerted its effect by direct interaction with chromatin. In additional experiments, A549 cells were prelabeled with 14 C-thymidine, treated with 25 μ M N-acetoxy-2-acetylaminofluorene (AAAF) for 15 min, and then incubated with and without 200 μ M HM. AAAF caused a rapid fragmentation of DNA that slowly reconstituted to the mol wt of untreated controls over 20-30 hr in the absence of HM. In the presence of HM, DNA fragmentation further increased during the first 4 hr, and slow elongation only occurred after 16 hr. Therefore, HM did not affect the immediate incision of damaged DNA, but it strongly inhibited a subsequent repair step. These results indicate that HM affects several processes that are thought to modify the mutagenic potency of procarcinogens and ultimate mutagens. (13 refs)

79-0747 Photosensitized Carcinogen Degradation and the Possible Role of Singlet Oxygen in Carcinogen Activation. (Eng) Greenstock, C. L. (Medical Biophysics Branch, Atomic Energy Canada Limited, Whiteshell Nuclear

Res. Establishment, Pinawa, Manitoba, Canada ROE 1LO); Wiebe, R. H. *Photochem Photobiol* 28(4/5): 863-867; 1978.

The dye sensitized photooxidation of various chemical carcinogens, including 2-acetylaminofluorene, benzo(a)pyrene, 9,10-dimethyl-1,2-benzanthracene and 4-nitroquinoline-N-oxide, was studied in the presence and absence of oxygen. Visible light from a filtered 150-watt Xe arc was used for photolysis, and carcinogen destruction was monitored spectrophotometrically. The carcinogens were solubilized in aqueous soln within micelles of various lipidlike surfactants. Photosensitized destruction of the carcinogens by several triplet sensitizers was observed. Enhanced damage in the presence of oxygen was also found. These results are consistent with the hypothesis that photochemical oxidative damage to carcinogens is produced in aerated soln via the sensitizer triplet state, possibly involving singlet oxygen. These manifold reactions are catalyzed by micelles that concentrate polycyclic hydrocarbons in the nonpolar environment within the micelles, where the exclusion of water probably increases reactive species lifetimes. This model photochemical system mimics the aerobic metabolic activation of chemical carcinogens, which is believed to be mediated partly by various forms of activated oxygen. (22 refs)

79-0748 Gas-Solid Chromatographic-Mass Spectrometric Confirmation of Low Levels of Acrylonitrile after Distillation from Food-simulating Solvents. (Eng) McNeal, T. (Div. Chemistry and Physics, Food and Drug Admin., Washington, DC, 20204); Brumley, W. C.; Breder, C.; Sphon, J. A. *J Assoc Off Anal Chem* 62(1): 41-46; 1979.

A gas-solid chromatographic-mass spectrometric method for confirming the presence of acrylonitrile (AN) monomer in food-simulating solvents is described. AN in aqueous food-simulating solvents is concentrated by adding methanol and distilling the AN-methanol azeotrope. AN in heptane is partitioned into water and azeotropically distilled with methanol. Levels as low as 0.01 ppm AN in the original food-simulating solvents can be confirmed. (5 refs)

79-0749 Malignant Transformation of Cryopreserved Early Passage Syrian Golden Hamster Cells by 2-(2-Furyl)-3-(5-nitro-2-furyl)acrylamide. (Eng) Pienta, R. J. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Lebherz, W. B.; Takayama, S. *Cancer Lett* 5(5): 245-251; 1978.

The malignant transformation of secondary cultures of Syrian golden hamster embryo cells prepared from cryopreserved primary cells by 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2) was studied. Each dish contained about 500 target cells seeded into 6×10^4 x-irradiated feeder cells. On the next day, AF-2 (0.05, 0.25, 0.5, 1.0, 2.0, or 5.0 μ g/ml) was added to the cultures, which were incubated for 8 days without re-

feeding. Typical morphological transformation was observed in three separate experiments. No transformation was seen in cultures treated with dimethyl sulfoxide or medium alone. The transformed cells grew in semisolid agar. Inoculation of nine nonimmunosuppressed suckling hamsters with 10^6 of these cells produced tumors as early as 9 days in some animals; all were positive at 63 days after inoculation. The tumors were spindle cell sarcomas or fibrosarcomas. Although a dose-response relationship was not observed, the system has merit for the qualitative determination of carcinogenicity. (12 refs)

79-0750 Carcinogenicity of N-Nitrosoephedrine in Rats. (Eng) Eisenbrand, G. (German Cancer Res. Center, Inst. Toxicology and Chemotherapy, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Preussmann, R.; Schmahl, D. *Cancer Lett* 5(2): 103-106; 1978.

The carcinogenicity of N-nitrosoephedrine (NED) was investigated in 32 male Sprague-Dawley rats administered the compound po (120 mg/kg 2x/wk). The first animal with forestomach (FS) papillomas died on day 374 after the beginning of the experiment. At this time, 22 animals were still alive. Of the remaining 21 animals, 13 died with tumors in the liver, lung, and FS and 2 with tumors at other sites. The overall tumor yield thus was 50%. The median time of death for the tumor-bearers was 522 days after the beginning of the experiment. All animals that died with hepatocellular carcinomas also showed lung metastases. In addition to the three animals that died with FS papillomas, one died with hyperkeratosis of the FS (day 583); another one with a hepatocellular carcinoma also had hyperplasia of the glandular stomach (day 588). The observation of hyperkeratosis, papillomas, and one squamous cell carcinoma of the FS suggests that the compound not only exhibits systemic effects, it is probably also a weak local carcinogen. There were no esophageal carcinomas, although NED is a close analog of a potent esophageal carcinogen. (4 refs)

79-0751 The Need for a Mammalian Test System for Mutagens: Action of Some Reducing Agents. (Eng) Stich, H. F. (Unit Environmental Carcinogenesis, B.C. Cancer Res. Centre, Vancouver, Canada); Wei, L.; Lam, P. *Cancer Lett* 5(4): 199-204; 1978.

The mutagenic activity of four reducing agents (cysteine, cysteamine, glutathione, and ascorbic acid) and hydrogen peroxide was tested in the *Salmonella typhimurium*/microsome mutagenicity test, in the DNA repair assay using human fibroblasts, and in the chromosome aberration test using Chinese hamster ovary cells. At nontoxic concentrations and in the presence and absence of Cu^{2+} , the test compounds did not significantly increase the frequency of mutations in the *Salmonella* test using strains TA98 and TA100. In the presence of Cu^{2+} , all of the test compounds induced

a marked DNA repair synthesis and a relatively high frequency of chromosome aberrations in cultured mammalian cells following a 3-hr exposure. The addition of catalase to the mixtures virtually eliminated the induction of DNA repair synthesis and greatly reduced the chromosome damaging effect of all four reducing agents. These results indicate that the use of several test subjects, including mammalian cells, is required to eliminate false negatives in mutagenicity screening. (13 refs)

79-0752 Danger from Aromatic Nitro- and Amino-Compounds. (Ger) Weber, H. (Werksarzt, Hoechst AG, 6230 Frankfurt/M.-Hochst, W. Germany). *Zentralbl Arbeitsmed Arbeitsschutz Proph* 28(8): 234-235; 1978.

Malignant bladder tumors are among the dangers of exposure to aromatic nitro and amino compounds. During 1967-1976, 17 cases of hemorrhagic cystitis and 5 bladder tumors that were caused by exposure to aromatic amino compounds were observed. Alcohol consumption enhances the toxicity of these compounds. (no refs)

79-0753 Analysis of N-Nitrosamines in Various Fruits and Vegetables. (Rus) Melamed, D. B. (Inst. Nutrition, Moscow, USSR); Kostiukovskii, Ia. L. *Vopr Pitan* (6): 64-69; 1978.

A fluorometric assay was employed for the routine evaluation of N-nitrosamines (NA) in various fruits and vegetables. The extractability of NA from plant samples ranged from 67.2% to 88.6%. Max levels of NA (up to 1.5 $\mu\text{g/kg}$) were detected in beets and radishes. It was concluded that the produce tested had relatively low levels of NA. (14 refs)

79-0754 Structure-Activity Relationships of Selected Nitrosamines. (Ger) Wenzel, U. (Sektion Pharmazie, Martin-Luther-Universität Halle-Wittenberg, Weinbergweg 15, DDR-402 Halle/Saale, E. Germany); Metzner, J. *Pharmazie* 33(11): 716-717; 1978.

Correlations between carcinogenicity and the physicochemical parameters of the substituents in N-nitrosodimethylamine, N-nitrosopyrrolidine, N-nitrosodiethylamine, N-nitrosoproline, N-nitrosodiamylamine, and N-nitrosodicyclohexylamine were studied. Carcinogenicity seems to increase with increasing lipophilia and molecule size. (8 refs)

79-0755 Significance of Nitrosamines in Animal Diets (Letter to Editor). (Eng) Edwards, G. S. (Cancer

Res. Div., Thermo Electron Corp., Waltham, MA, 02154); Fox, J. *Science* 203(4375): 6; 1979.

In a reply to a previous criticism, it is stressed that the contamination of laboratory animal feeds with up to 50 ppb N-nitrosodimethylamine (NDMA) can have a synergistic action with other (test) carcinogens, a statement supported by the literature. In addition, the study showed that 10 ppb NDMA in the drinking water of A/J mice during the fetal, weaning, and postweaning period up to 22 wk of age tripled lung tumor incidence from 8% to 23%. (5 refs)

79-0756 Dimethylnitrosamine-induced Structural Damage to DNA Results from Repair of O⁶-Methylguanine Rather than Repair of 7-Methylguanine. (Eng) Huang, P. H. (Sch. Pathology, Univ. New South Wales, P.O. Box 1, Kensington, N.S.W. 2033, Australia); Stewart, B. W. *Cancer Lett* 5(3): 161-166; 1978.

The hypothesis that single-stranded regions of DNA associated with the repair of O⁶-methylguanine (O-MG) are more readily bound to benzoylated diethylaminoethyl (DEAE)-cellulose than single-stranded regions associated with repair of 7-methylguanine (7-MG) was investigated by analyzing DNA labeled with ¹⁴C-dimethylnitrosamine (DMN) following primary fractionation on this cellulose. Female Wistar rats were injected ip with 10 mg/kg ¹⁴C-DMN (a nonnecrotizing dose) and sacrificed 4 or 24 hr later. DNA isolated from pooled livers was sheared and fractionated by chromatography on benzoylated DEAE-cellulose. Preparations of native DNA (NaCl-eluted) and DNA containing single-stranded regions (caffeine-eluted) were hydrolyzed and amounts of methylated guanine determined. Four hours after DMN injection, there was no difference in the distribution of 7-MG and O-MG between the two DNA fractions. At 24 hr, the amounts of 7-MG were still not different, but there was 10 times less O-MG in the caffeine-eluted DNA. This virtual absence of O-MG from caffeine-eluted DNA at this time implies that binding to benzoylated DEAE-cellulose was due exclusively to repair of O-MG. The qualitative distinction in the repair processes at 24 hr, defined in terms of the binding of particular single-stranded regions to benzoylated DEAE-cellulose, could be due to difference in size of the respective single-stranded regions and/or longer persistence of O-MG-derived single-stranded regions compared with those for 7-MG. (29 refs)

79-0757 DNA Repair Synthesis in Primary Cultures of Kidneys from BALB/c and C3H Mice Treated with Dimethylnitrosamine. (Eng) Brambilla, G. (Dept. Pharmacology, Univ. Genoa, Genoa, Italy); Cavanna, M.; Carlo, P.; Finollo, R. *Cancer Lett* 5(3): 153-159; 1978.

An in vivo-in vitro autoradiographic method was devised to study DNA repair in the kidneys of male BALB/c and C3H

mice following a single ip injection of dimethylnitrosamine (DMN: 38, 75, 150, or 300 mg/kg). Two hours after injection, kidneys were removed, minced, and 10,000 glomeruli and tubule fragments were incubated in culture with 1 μ Ci/ml ³H-thymidine. The level of unscheduled DNA synthesis was subsequently evaluated autoradiographically. Whereas unscheduled DNA synthesis was dose-dependent in the kidney cultures of both DMN-treated strains, it was practically absent in the cultures of control mice. The amount of synthesis was positively correlated with the differential susceptibility of C3H and BALB/c mice to kidney tumor induction by DMN, and it was 3 and 2.6 times higher in cultures from the former at 38 and 75 mg/kg, respectively. (22 refs)

79-0758 Dimethylnitrosamine Demethylase Activity of Rat Liver Microsomes after Partial Hepatectomy. (Eng) Evarts, R. P. (Carcinogen Metabolism and Toxicology Branch, NCI, NIH, Bethesda, MD, 20014); Mostafa, M. H. *Biochem Pharmacol* 27(23): 2751-2753; 1978.

The reason for the increased hepatocarcinogenicity of dimethylnitrosamine (DMN) following partial hepatectomy (PH) was investigated by determining liver DMN demethylase levels in male Wistar rats at 6, 24, 48, and 72 hr after median and left lateral lobe PH. In addition, the LD₅₀ for DMN administered 1 day after PH (50-156 mg/kg ip) was compared with that of control animals. The number of dead animals was recorded 44 hr after the injection, and the LD₅₀ was calculated from probit regression lines. Enzyme activity began to decrease at 6 hr post-PH and reached its lowest point (47%) at 24 hr; however, at 48 hr it had returned to approx 90% of control values. The LD₅₀ at 44 hr after injection was 114 mg/kg for PH animals and 82 mg/kg for controls. The reduced enzyme activity after PH indicates that increased DMN carcinogenicity after this operation is not caused by a compensatory increase in demethylase activity associated with liver regeneration. Rather, the results favor the idea that a slowing of DMN metabolism, while protecting against the acute toxicity of the drug, is a predisposing factor for carcinogenicity. (28 refs)

79-0759 Effects of N-Nitrosodiethylamine on Murine Hepatic Mixed-Function-Oxidase Activities. (Eng) Tucker, A. N. (Dept. Pharmacology, Medical Coll. Virginia, Richmond, VA, 23298); Tang, T.; Friedman, M. A. *J Environ Pathol Toxicol* 2(2): 571-578; 1978.

The effects of N-nitrosodiethylamine (DEN, 25-400 mg/kg po 24 hr before sacrifice, or 50 ppm in the drinking water for 12 wk) on the mixed-function oxidase activities of mouse liver were studied in male BALB/c mice. A single po dose of DEN resulted in a significant reduction in cytochrome P-450, aminopyrene demethylase, aniline hydroxylase, and DMN demethylase. The max effect was seen with 100 mg/kg DMN. Similar effects were observed in animals given DEN

in the drinking water for 12 wk. When S-9 fractions from the livers of mice treated with DEN were used to activate aflatoxin B₁, benzo(a)pyrene, and 2-acetylaminofluorene to mutagens in the Ames Salmonella mutagenesis test, activation was equivalent to or greater than that obtained using control S-9 fractions. The effects of DEN on aminopyrene demethylase could not be reproduced by collecting microsomes from homogenates that had been treated in vitro with DEN. The data support the concept that alteration of microsomal enzyme activities is an important effect of DEN. (13 refs)

79-0760 Genetic Activity of Chemicals in Yeast: DNA Alterations and Mutations Induced by Alkylating Anti-cancer Agents. (Eng) Ruhland, A. (Arbeitsgruppe Mikrobengenetik, Johann Wolfgang Goethe-Universitat, Robert-Mayer-Strasse 7-9, 6000 Frankfurt am Main, W. Germany); Fleer, R.; Brendel, M. *Mutat Res* 58(2/3): 241-250; 1978.

The alkylating anticancer agents nitrogen mustard, chlorambucil, triaziquone, activated cyclophosphamide, and half-mustard (2-dimethylaminoethylchloride) were tested for ability to produce primary DNA lesions and mutagenicity in *Saccharomyces cerevisiae* strains MB1072-2B, MB1113-8C, MB1114-5D, MB1114-16D, and MB1034-5A. Cross-links were detected by ultracentrifugation of the DNA in a neutral cesium chloride equilibrium density gradient. The formation of cross-links was correlated with time of application and with concentration of the alkylating agent. Nitrogen mustard was highly mutagenic in fully repair-proficient cells, less mutagenic in excision-deficient cells, even less so in postreplication repair-deficient cells, and was virtually nonmutagenic in cells lacking the excision-repair function. All the other mono-, bi-, and trifunctional alkylating agents tested were both mutagenic and lethal to differing extents. It appears that measurement of DNA interstrand cross-links is one of the more sensitive methods for detecting the genetic activity of polyfunctional alkylating agents. (36 refs)

79-0761 Induction of Thyroid Follicular Adenomas and Carcinomas by N-Nitrosobis(2-oxopropyl)amine. (Eng) Pour, P. (Eppley Inst. Res. Cancer; Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB 68105); Salmasizadeh, S. *Cancer Lett* 5(1): 13-18; 1978.

Thyroid follicular adenomas and carcinomas developed in MRC rats treated with N-nitrosobis(2-oxopropyl)amine (BOP) in a single dose (100 mg/kg sc) or in weekly doses (2.5, 5, or 10 mg/kg sc) for life. The single dose produced a tumor incidence of 0/1 in females and 2/4 in males; the respective weekly doses produced incidences of 9/15, 2/15, and 2/15 in females and 6/15, 5/15, and 6/15 in males. Tumor incidence was slightly higher and the latency period shorter in males, but the tumors were larger in females. No dose-re-

sponse relationship was seen. The actual tumor incidence may have been higher, as the small size of most of the neoplasms (1-2 mm) made them difficult to detect. In all, 32 rats developed 48 thyroid neoplasms, most of which were located in the midportion of the organ. Tumors were solid in 20 rats and multiple in 12. Morphologically, 38 tumors were adenomas (including follicular, papillary, follicular-papillary, and solid types) and 10 were carcinomas (follicular, follicular-papillary, and solid types). The possible mechanisms of BOP carcinogenesis are discussed. This experiment provides a model for investigating thyroid tumor etiology and an opportunity to elucidate the complexity of nitrosamine carcinogenicity. (13 refs)

79-0762 An Animal Model of Pancreatic Cancer Involving Whole Pancreas Transplantation. (Eng) Sayers, H. J. (Dept. Surgery, Univ. California Sch. Medicine, San Diego, CA); Dail, D. H.; Orloff, M. J. *Surg Forum* 29: 122-124; 1978.

Transplantation of the pancreas obtained from Syrian hamsters treated with 2,2'-dihydroxydi-n-propylnitrosamine (12.5 mg/wk, sc) for 18 wk into healthy recipients as a heterotopic, vascularized, pancreaticoduodenal isograft or more provides a unique model of metastasizing pancreatic cancer that resembles the human disease. (2 refs)

79-0763 Mutagenicity of Aliphatic Nitrosamines in *Salmonella typhimurium*. (Eng) Rao, T. K. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN, 37830); Young, J. A.; Lijinsky, W.; Epler, J. L. *Mutat Res* 66(1): 1-7; 1979.

The mutagenicity of 25 aliphatic nitrosamines was assayed using *Salmonella typhimurium* strains TA1535, TA100, TA1537, and TA98 with and without metabolic activation (MA) by rat liver homogenates. All mutagenicity analyses included both a plate assay and a liquid suspension test. With the exception of the halogenated compounds, all of the nitrosamines required MA, with a preference for the phenobarbital-induced rat liver homogenate. Only two test compounds, nitrosobis(2-chloroethyl)amine and nitrosobis(2-chloropropyl)amine, were mutagenic without MA. Of the remaining compounds, nine were mutagenic after MA: diethylnitrosamine, di-n-propylnitrosamine, nitrosodi-n-butylamine, nitrosodiisobutylamine, nitrodiallylamine, nitrosobis(2-ethoxyethyl)amine, nitrosomethyl-2-phenylethylamine, nitrosoethylethanolamine, and nitrosodi-n-octylamine. The last two compounds had borderline activity. However, two compounds not carcinogenic in rats were mutagenic and nine carcinogens were not mutagenic, including six that are liver carcinogens in rats. Thus, the suggested close relationship between carcinogenicity and mutagenicity, as determined in the liver mi-

chrome-activated *Salmonella* test, is not supported by these results. (19 refs)

79-0764 **Carcinogenicity of Methylated Derivatives of N-Nitrosodiethylamine and Related Compounds in Sprague-Dawley Rats.** (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Taylor, H. W. *J Natl Cancer Inst* 62(2): 407-410; 1979.

The carcinogenicity of four nitrosamines derived by substitution of methyl groups for hydrogen in N-nitrosodiethylamine (NDEA) was tested by administration to Sprague-Dawley rats in drinking water at approx equimolar concentrations (0.7-0.9 mM). Treatments were given on 5 days/wk for 30 or 50 wk, and animals were allowed to diet naturally or were killed when moribund. Although N-nitrosohexamethylenimine (NHMI: a cyclic nitrosamine tested for comparison) and N-nitrosodi-n-propylamine (NDPA) both produced a spectrum of tumors similar to NDEA, the former was the stronger carcinogen, being equally potent as NDEA and killing all treated animals by 40 wk. All these animals had tumors of the liver, esophagus, or nasal turbinates, and many had tumors in multiple sites, but NDPA-treated rats had a greater number of carcinomas of the esophagus than NHMI-treated rats, and NDPA induced only hepatocellular carcinomas in the liver, whereas NHMI produced mostly hemangioendothelial sarcomas. N-Nitrosodiisopropylamine was a comparatively weaker carcinogen, inducing only a significant number of tumors of the nasal turbinates. At the doses given, neither N-nitrosodiisobutylamine or N-nitrosodi-sec-butylamine was significantly carcinogenic. These results support the hypothesis that oxidation at the alpha carbon atom of nitrosamines is a significant step in carcinogenicity. (17 refs)

79-0765 **Liver Ornithine Decarboxylase During Phenobarbital Promotion of Nitrosamine Carcinogenesis.** (Eng) Farwell, D. C. (Inst. Medical Res., Camden, NJ, 08103); Nolan, C. E.; Herbst, E. J. *Cancer Lett* 5(3): 139-144; 1978.

The hypothesis that elevation of ornithine decarboxylase (ODC) is a specific and possibly essential biochemical event in the promotion of skin tumors was tested in Sprague-Dawley rats. The rats were fed a 25% casein diet and drinking water containing 40 ppm N-diethylnitrosamine (DEN) ad libitum for 4 wk, at which time DEN was discontinued and phenobarbital (PB: 500 ppm in the diet) was begun for up to 20 wk (Group 4). Other groups received the casein diet only (Group 1), casein diet + PB (Group 2), or DEN + casein diet (Group 3). PB was very effective in promoting liver tumors induced by DEN, as Group 4 animals had a tumor incidence of approx 80% vs 33% in Group 3. There was no observable alteration in ODC activity in the tumor tissue of

either of these groups compared with enzyme activity in normal liver tissue. The hepatic concentrations of spermine and spermidine were similarly unchanged. Therefore, the promotion of hepatocarcinogenesis by PB does not appear to encompass phenotypic changes that induce or maintain elevated ODC activity in the liver. (10 refs)

79-0766 **Carcinogenesis of Nitrosomethylundecylamine in Fischer Rats.** (Eng) Lijinsky, W. (Frederick Cancer Res. Center, P.O. Box "B", Frederick, MD, 21501); Taylor, H. W.; Mangino, M.; Singer, G. M. *Cancer Lett* 5(4): 209-213; 1978.

Nitrosomethylundecylamine (NMUA) was synthesized and administered to Fischer 344 rats by gavage in olive oil soln (23 mg/animal 2x/wk for 30 wk). Nineteen rats died with tumors in the liver and/or lung. In contrast to the activity of its homolog, nitrosomethyldodecylamine (NMDA), no bladder tumors were induced. The liver tumors were hepatocellular carcinomas and cholangiocarcinomas, and they were first seen in animals dying at 40 and 45 wk, respectively. The lung tumors were squamous cell carcinomas (the first at 43 wk) and alveolar cell adenomas and adenocarcinomas (the first at 42 wk). There were also two animals with esophageal squamous cell carcinomas and two with papillomas of the nonglandular stomach. The large difference in target sites for tumor induction between NMUA and NMDA is consistent with the hypothesis that the long even-numbered carbon chain of the latter is degraded by beta oxidation to a 4-carbon chain, which is the proximate carcinogen. Similar degradation of the undecyl chain would result in a 3-carbon chain. (8 refs)

79-0767 **Comparison of Bladder Carcinogenesis by Nitrosomethyldodecylamine in Sprague-Dawley and Fischer Rats Carrying Transplanted Bladder Tissue.** (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Taylor, H. W. *Cancer Lett* 5(4): 215-218; 1978.

A comparison was made of nitrosomethyldodecylamine (NMDA) carcinogenesis in male and female Sprague-Dawley and Fischer 344 rats, each of which bore a portion of urinary bladder transplanted beneath the skin of the back. NMDA was given to each animal by gavage (25 mg in olive oil 2x/wk for 30 wk; total dose: 1,500 mg/rat). In animals in which the transplants survived until death, there was only one tumor, an anaplastic carcinoma in one of the Sprague-Dawley rats. A solid growth of epithelial cells that was interpreted as possibly being of preneoplastic significance was found in a second Sprague-Dawley rat. No tumors were present in the transplants in Fischer rats. There was a 100% incidence of transitional cell carcinomas in all host urinary bladders. A large percentage of the bladder tumors metastasized to the lungs. The Fischer rats appeared to be more sensitive than the Spra-

gue-Dawley rats to NMDA, since they died earlier of transitional cell carcinomas of the bladder. The bladder tumor appears to be the only neoplastic response of these two rat strains to NMDA, with no detectable lesions in the liver or other organs. (7 refs)

79-0768 Epithelial Alterations in Fetal Tracheal Explants of Syrian Golden Hamsters Exposed to Diethylnitrosamine In Utero. (Eng) Emura, M. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Richter-Reichhelm, H. B.; Mohr, U. *Cancer Lett* 5(2): 115-121; 1978.

The neoplastic effect of diethylnitrosamine (DEN) on fetal tracheal epithelia after transplacental exposure was determined by a combined in vivo-in vitro approach. Pregnant Syrian golden hamsters were injected ip with 200-400 mg/kg DEN on day 13, 14, or 15 of gestation. Fetuses were removed 3.5-4 hr after exposure. Fetal tracheas were dissected, divided into cranial and caudal portions, and incubated in organ culture for 4-6 wk. After intrauterine DEN exposure, the fetal tracheal explants were macroscopically similar to those of control animals for up to 25 days of cultivation. Between 25 and 42 days, however, 48/74 experimental specimens developed lesions of the epithelial lining, and they consisted of hyperplasia, focal squamous cell metaplasia, and dysplasia. These lesions were found more frequently in cranial explants (29/37) than in caudal explants (19/37), and the differences were most distinguishable in explants exposed to DEN on gestation day 15. No alterations occurred in the control explants. These findings support the view that cellular differentiation partially determines the susceptibility of the hamster's respiratory epithelium to the effects of chemical carcinogens such as DEN. (14 refs)

79-0769 Transplantable Ductal Adenocarcinoma of the Syrian Hamster Pancreas. (Eng) Scarpelli, D. G. (Dept. Pathology, Northwestern Univ., 303 E. Chicago Ave., Chicago, IL, 60611); Rao, M. S. *Cancer Res* 39(2, Part 1): 452-458; 1979.

Growth, morphology, and biochemical characteristics of a well-differentiated ductal adenocarcinoma induced in a female Syrian golden hamster by N-nitrosobis(2-oxopropyl)amine and transplanted surgically into the dorsum of weanling nude athymic male BALB/c mice and into the inguinal region of weanling inbred Syrian hamsters are described. The tumor grew rapidly in nude mice (12-fold size increase by 45 days) with metastases being common, while growth in the hamster was slow (3-fold increase by 45 days) with no metastases seen. Although the tumor largely retained morphological characteristics of a well differentiated adenocarcinoma after 4 or 5 passages in vivo in both species, an intense infiltration of the tumor by polymorphonuclear leukocytes without

necrosis or infection being present was noted in the hamster. The tumors produced mucin and rapidly and specifically bound ^{125}I -labeled secretin, although the degree of nonspecific binding was higher than that of control hamster pancreas (40.5% vs 23%, respectively). Unstimulated adenyl cyclase activity of the neoplasm was significantly greater than that of unstimulated normal hamster pancreas. Although secretin administration increased the level of 3'/5'cyclic AMP three-fold in pancreas of normal hamsters, it did not significantly change this level in neoplastic tissue. These results suggest the secretin receptors on the cell membranes of the neoplasm may be altered in comparison with normal pancreas. (47 refs)

79-0770 Formation of N-Nitroso Compounds from Drugs and Nitrite in Human Gastric Juice In Vitro. (Ger) Scheunig, G. (Zentralinstitut für Krebsforschung, Akademie der Wissenschaften, Lindenberger Weg 80, DDR-1115 Berlin-Buch, E. Germany); Ziebarth, D. *Pharmazie* 33(11): 722-726; 1978.

The in vitro formation of N-nitroso compounds from 36 drugs containing tertiary amines as the active agent and from sodium nitrite was studied in the gastric juice of pentagastrin-stimulated humans. Nitrosamines (NA's) formed with four drugs: aminophenazone (APZ: concentration 120 mg/100 ml; NA yield 69%), Copyrkal (a commercial preparation of APZ: concentration 30 mg/100 ml, NA yield 43%), Analgin (methampyrone: concentration 100 mg/100 ml; NA yield 11%), and Bromhexin (bromohexine hydrochloride: concentration 5 mg/100 ml, NA yield 3%). The NA formation rate was highest at pH 2.0. APZ and Copyrkal formed nitrosodimethylamine and an unidentified NA, but Analgin and Bromhexin yielded only one unidentified NA each. The reaction between APZ, Copyrkal, or Bromhexin and the nitrite was completed in 25 min, that between Analgin and the nitrite in 1 min. The nitrite consumption of eight compounds that are able to compete with amines in the nitrosation reaction (amidosulfonic acid, ascorbic acid, urea, glutamine, glycine, ethylurethane, ethanolamine, and ammonium chloride) was investigated at different pH's. Only ascorbic acid and amidosulfonic acid showed considerable nitrite consumption. Although the nitrite consumption of ascorbic acid was practically independent of pH in the range of 2-5, that of amidosulfonic acid declined with rising pH. (51 refs)

79-0771 Development of Biliary and Hepatic Neoplasms in Guinea Pigs Treated with N-Nitrosobis(2-oxopropyl)amine. (Eng) Rao, M. S. (Dept. Pathology, Northwestern Univ. Medical Sch., 303 E. Chicago Ave., Chicago, IL, 60611); Pour, P. *Cancer Lett* 5(3): 31-34; 1978.

The carcinogenicity of N-nitrosobis(2-oxopropyl)amine (BOP), a potent pancreatic carcinogen in Syrian golden ham-

sters, was studied in male inbred strain 13 guinea pigs. A group of 29 animals was given two weekly doses of 70 mg/kg sc during weeks 1 and 2 followed by two weekly doses of 20 mg/kg during weeks 4 and 5, for a total cumulative dose of 65-78 mg BOP. Animals were observed until death or termination of the experiment at 55 wk. Of the 14 guinea pigs surviving beyond 30 wk, 7 developed cholangiocarcinomas and 2 hepatocellular carcinomas. Eight of these animals also had hyperplastic foci or nodules. Metastases to peritoneal fat were seen in two animals with cholangiocarcinomas and to the lungs in one with hepatocellular carcinoma. The livers of the 15 animals that died before 30 wk were pale, and many had multiple cystic lesions that increased in number over time. There was marked bile and oval cell proliferation in these animals plus fatty metamorphosis, hepatic cell necrosis, and hepatocyte intranuclear inclusions. Cholangiofibrosis was common (41%) in animals dying after 15 wk. Cholangiomas first appeared at 6 wk and reached an eventual incidence of 69%. No tumors were found in other organs and no changes were noted in the pancreas, which indicates that BOP is not a pancreatic carcinogen in the guinea pig. (19 refs)

79-0772 Chemical and Biological Implications of Organic Compounds Formed in Simulated and Real Urban Atmospheres. (Eng) Pitts, J. N. (Dept. Chemistry, Univ. California Statewide Air Pollution Res. Center, Riverside, CA, 92521). *Ecotoxicol Environ Safety* 2(2): 199-217; 1978.

To evaluate the health effects, atmospheric sources, transformations, and sinks of a variety of nitrogenous compounds and polycyclic aromatic hydrocarbons (PAH) in accordance with the US Clean Air Act, research was conducted on real and simulated urban atmospheres. A 50-meter³ outdoor chamber was used to monitor the reactions in air of approx 500 ppb of diethylamine or triethylamine (DEA or TEA) with 10-20 ppb of NO and NO₂ and trace amounts of HONO. Results of gas chromatography-mass spectrometry product analysis revealed that diethylnitrosamine (DEN) was readily formed from DEA in the dark (approx 3% yield) and destroyed by sunlight, whereas traces of DEN formed from TEA in the dark showed an increased yield (approx 2%) in sunlight. Other photo-oxidation products from both amines included known carcinogens such as dimethylnitrosamine and acetamide. In a separate experiment, species such as N₂O₃, HNO₃, HONO, CH₃ONO₂, HO₂NO₂, HCOOH, and H₂CO were identified by high-resolution Fourier transform-infrared spectroscopy (FT-IR) when a mixture of air, propylene, and NO, was irradiated by a solar simulator. With a second FT-IR spectrometer, ppb levels of HNO₃, NH₃, HCOOH, and H₂CO were identified in "aged" ambient photochemical smog. When organic extracts of ambient particulates were subjected to the Ames' *Salmonella typhimurium* assay, all of them showed frameshift-type mutagenic activity without metabolic activation. The results show that these urban samples must contain mutagens other than those that require treatment with S-9 liver homogenate for activity in the Ames'

test, and therefore it is suggested that these active mutagens are formed in atmospheric reactions of ambient PAH with compounds present in photochemical smog. (42 refs)

79-0773 Two Crops of Primary Lung Tumors in BALB/c Mice after a Single Transplacental Exposure to Urethane. (Eng) Anderson, L. M. (Walker Lab., Memorial Sloan-Kettering Cancer Center, Rye, NY, 10580). *Cancer Lett* 5(1): 55-59; 1978.

The induction of lung tumors by transplacental exposure to urethane was studied in BALB/c mice. Pregnant mice were injected with urethane (1 mg/g ip) on gestation day 17. The offspring were sacrificed at age 10-54 wk, and a complete necropsy was performed. Only lung adenomas were found. Tumor incidence was 3/25 mice aged 12 wk, 1/17 aged 36 wk, 2/8 aged 38-42 wk, and 9/17 aged 1 yr. The latter incidence was significantly greater than that in mice age 10-36 wk. The results suggest that most lung tumors resulting from urethane treatment did not appear until age 8-12 mo. There were, therefore, two distinct crops of tumors. The fact that the second crop arose coincidentally with the first spontaneous tumors in controls (age 38-40 wk) and at the time when aging begins in the mouse suggests involvement of age-related changes in the host. Aging-associated changes in immune system function may have stimulated the growth of latent lung tumors. Immunostimulation of slow-growing, weakly antigenic tumors may also account for the appearance of the second crop. The system used may be useful for studying tumor latency. In addition, the results suggest that carcinogenesis assays based on lung tumors in certain mouse strains should be of sufficient duration. (15 refs)

79-0774 Mutagenic Action of N-Nitroso Derivatives of Carbamate Insecticides (Carbaryl and Propoxur) on Mammalian Cells. (Pol) Tyrkiel, E. (Zaklad Toksykologii Sanitarnej, Panstwowy Zaklad Higieny, ul. Chocimska 24, 00-791 Warsaw, Poland); Palut, D.; Cybulski, J. *Rocz Panstw Zakl Hig* 29(5): 527-532; 1978.

The mutagenicity of N-nitrosopropoxur (single dose of 100-300 mg/kg po) and of N-nitrosocarbaryl (50-150 mg/kg ip) was studied in Wistar rats and mice, respectively. These compounds failed to induce chromosome aberrations in the bone marrow cells of the animals. (12 refs)

79-0775 Carcinogenic Effect of N-Nitrosobis(2-hydroxypropyl)amine in Rabbits. (Eng) Kondo, H. (Dept. Oncological Pathology, Cancer Center, Nara Medical Univ., 840 Shijocho, Kashihara, Nara 634, Japan); Ikeda, T.; Yoshimura, Y.; Hoshimura, H.; Konishi, Y. *Cancer Lett* 5(6): 339-343; 1978.

The carcinogenic effect of N-Nitrosobis(2-hydroxypropyl)amine (BHP) was studied in 2.5- to 3-mo-old male rabbits. Six rabbits were given 1,000 ppm BHP in their drinking water for 25 wk (av intake, 40.6 mg BHP/day), and the survivors were sacrificed 60 wk after the start of treatment. Five BHP-treated rabbits survived > 50 wk, and 4/5 had liver and lung tumors. All six control rabbits survived for 60 wk, and none developed tumors. The liver tumors were hepatocellular adenomas, hemangiomas, and angiosarcomas. The lung tumors were adenomas and hemangiomas. Massive liver cell necrosis was seen in the treated rabbit that died at 31 wk. The BHP effect in rabbits differs from that reported in hamsters, but it is similar to that in mice, rats, and guinea pigs. These results support the view that the carcinogenic effect of nitroso compounds is influenced by chemical properties or by tissue-specific and species-specific factors as well as by route of administration. (11 refs)

79-0776 Pulse Polarographic Determinations of Nitrosamines. Part I. Determination of N-Nitrosodiethanolamines in Grinding Fluids. (Eng) Samuelsson, R. (Dept. Analytical Chemistry, Univ. Umea, S-901 87 Umea, Sweden). *Anal Chim Acta* 102(1): 133-140; 1978.

Assessment of differential pulse polarography for the direct determination of N-nitrosodiethanolamine (NDEA) in aqueous media revealed that the optimum supporting electrolyte and pH were H_2SO_4 at pH 1-2. The detection limit was approx 5×10^{-8} M NDEA. When the procedure was applied to commercial grinding fluids, high NDEA levels were found (75 μM) with an accuracy > 92% and a precision of $\pm 8\%$. (22 refs)

79-0777 Comutagenic Effects Exerted by N-Nitroso Compounds. (Eng) Guttenplan, J. B. (New York Univ. Dental Center, New York, NY, 10010). *Mutat Res* 66(1): 25-32; 1979.

The effect of pretreatment with dimethylnitrosamine (DMN), N-methyl-N-nitrosourea (NMU), or N-ethyl-N-nitrosourea (NEU) on the sensitivity of *Salmonella typhimurium* strains TA100 and TA1530 to mutagenesis with other N-nitroso compounds was tested. Mutagenesis induced by DMN and NMU alone was characterized by biphasic dose- and time-response curves. At low concentrations of NMU (0.10 and 0.35 mM) or short incubation times with DMN (5 and 10 min), no mutagenic response was observed, but higher doses of NMU (1.0, 2.5, and 5.0 mM) or longer incubation times with DMN (20, 30, or 40 min) led to substantially increased mutagenesis. Bacteria pretreated with subthreshold doses of DMN, NMU, or NEU were more sensitive to several mutagens than untreated bacteria. NMU sensitized bacteria toward DMN, diethylnitrosamine, or NEU; DMN sensitized bacteria toward NMU; and NEU enhanced subsequent mutagenesis by NMU. Mutagenesis induced by methyl-methane-

sulfonate and N-propyl-N'-nitro-N-nitrosoguanidine was not significantly enhanced by NMU or NEU pretreatment, suggesting that the former mutagens act by different mechanisms. The growth phase of the bacteria had little effect on the percentage enhancement of mutagenesis caused by pretreatment. These results suggest that an important role for N-nitroso compounds in the initiation of mutagenesis and carcinogenesis may be one of sensitization. (25 refs)

79-0778 Phase-Specific Cytotoxicity In Vivo of Hydroxyurea on Murine Fibrosarcoma Cells Synchronized by Centrifugal Elutriation. (Eng) Grdina, D. J. (Section Experimental Radiotherapy, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030); Sigdestad, C. P.; Peters, L. J. *Br J Cancer* 39(2): 152-158; 1979.

The S-phase-specific cytotoxicity of hydroxyurea (HU: 1 mg/ml, ip) was tested using synchronized murine fibrosarcoma (FSa) cells lodged in the lungs of female CeHf/Bu mice. FSa cells from primary asynchronous cultures were separated and synchronized on the basis of size by centrifugal elutriation. Flow microfluorometry (FMF) was used to determine the cell-cycle parameters and the relative synchrony of the separated populations. After elutriation, FSa cells from each fraction and heavily irradiated unseparated tumor cells were injected iv into whole-body irradiated mice, and HU was injected 20 min later. The unseparated control population number was reduced 35% and the S-phase cells were reduced 33% by HU. In general, there were no appreciable differences in lung colony number in any of the elutriated control groups. HU reduced lung colonies to some extent in all mice except those injected with fractions containing largely G_1 cells. The max reduction (80%) in lung colonies occurred in mice injected with the cell fraction containing the larger percentage (65%) of S-phase cells. The results demonstrate the usefulness of this procedure as a rapid method for characterizing the phase specificity of chemotherapeutic drugs in vivo. (10 refs)

79-0779 Stimulation of Ultraviolet-induced Carcinogenesis by 1,3-Bis(2-chloroethyl)-1-nitrosourea. (Eng) Epstein, J. H. (Dept. Dermatology, Univ. California Sch. Medicine, San Francisco, CA, 94143). *Cancer Res* 39(2, Part 1): 408-410; 1979.

To evaluate the effect of noncarcinogenic levels of 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) on the induction of cutaneous squamous cell carcinoma by carcinogenic levels of UVB radiation, 145 3- to 4-mo-old female HR hairless mice were divided into 4 treatment groups; Group 1 (40 mice) received topical applications of BCNU (0.5 mg in 0.1 ml acetone, 1x/wk) and UVB energy (1.25×10^3 millijoules/cm² 3x/wk) to the posterior half of their backs for the duration of the study (up to 13 mo); Group 2 (36 mice)

received acetone applications and UVB exposures; Group 3 (29 mice) received BCNU treatment only; and Group 4 (40 mice) received acetone applications only. Mice were examined regularly, and mice with tumors > 4 , > 50 , and > 100 mm³ were tabulated. No tumors occurred in Groups 3 or 4, but 100% of the Group 1 survivors and 94% of the Group 2 survivors developed tumors. Tumors > 4 mm³ occurred by 2.25 mo in Group 1 and by 2.5 mo in Group 2; tumors > 50 mm³ occurred by 3 mo in both groups; tumors > 100 mm³ occurred at 3 mo in Group 1 and at 3.25 mo in Group 2. There were 1.3 and 1.4 tumors/mouse in Groups 1 and 2, respectively. Most of the tumors > 4 mm³ appeared earlier in Group 1 (before 8 mo) than in Group 2 (before 10 mo) and grew more rapidly in Group 1 than in Group 2, indicating that BCNU had a promoting or cocarcinogenic effect on UVB-induced carcinogenesis. It is concluded that BCNU + UV induces tumors of all three sizes more rapidly than does acetone plus UV. Therefore, patients being treated with topical BCNU should avoid extensive sun or artificial UV irradiation. (18 refs)

79-0780 Genetic Basis of Susceptibility for Neuroblastoma Following Treatment with N-Methyl-N-nitrosourea and X-rays in *Xiphophorus*. (Eng) Schwab, M. (Genetisches Institut der Justus-Liebig-Universität Gießen, Heinrich-Buff-Ring 58-62, D-6300 Giessen, W. Germany); Kollinger, G.; Haas, J.; Ahuja, M. R.; Abdo, S.; Anders, A.; Anders, F. *Cancer Res* 39(2, Part 1): 519-526; 1979.

The susceptibility of 65 genotypes of *xiphophorus* (nonhybrids and interpopulational and interspecific F₁ and backcross hybrids) to neuroblastoma (NB) development following exposure to N-methyl-N-nitrosourea (MNU: 1 mM in aquarium water for 1 hr, 4x at 2-wk intervals) or whole-body x-irradiation (1,000 R for 45 min, 3x at 6-wk intervals) was studied. NB's were induced in 64/3,500 fish by MNU and in 4/5,500 fish by x-rays; no NB's were noted in equal numbers of control fish. A group of backcross genotypes carrying the "lineatus" chromosome was particularly susceptible, as 60/64 MNU-induced and all 4 radiation-induced NB's developed in the 605 and 859 respectively treated fish in this group. These fish were derived from *X. variatus* x *X. helleri* hybrids with the latter as the recurrent parent. NB's could not be induced in *X. variatus* or in the F₁ generation of (*X. variatus* x *X. helleri*), although both carry the lineatus chromosome, in *X. helleri*, which lacks this chromosome, or in lineatus-lacking segregants. The results imply that NB is triggered by somatic mutation of regulating genes suppressing another gene (located on the lineatus chromosome) that favors neoplastic transformation. The number of regulating genes may account for the differential susceptibility of fish carrying this chromosome. Susceptibility would be due to a monogenic regulating system, which can be impaired easily by a single mutation; this system can be produced by eliminating regulating genes during selective backcrossing. (59 refs)

79-0781 N-Ethyl-N-nitrosourea-induced Teratogenesis of Brain in the Rat. A Cellular and Cytoarchitectural Analysis of the Neocortex. (Eng) Hallas, B. H. (Dept. Biological Sciences, Purdue Univ., West Lafayette, IN, 47907); Das, G. D. *J Neurol Sci* 39(1): 111-122; 1978.

N-Ethyl-N-nitrosourea (ENU: 60 mg/kg) was administered iv to pregnant Wistar rats on gestation days 14-21 to study the effects of the carcinogen on the developing brain. Overall brain size, size of the neocortex, and number of nerve cells per slab of neocortex were reduced by ENU treatment. The effects were graded, being more severe in pups treated early in embryogenesis than in those treated late in gestation. The following histologic abnormalities also occurred in a graded fashion: reduction in the number of nerve cells with a resulting thinning of all six layers of the neocortex; reduction in the size of the perikarya from different layers; increased density of nerve cells in the neocortex; patchy distribution of hyperchromatic cells in the neocortex; reduction in the number of dendrites per pyramidal cell; and reduction in the length, thickness, and branching of dendrites. The orientation of the pyramidal cells and other neocortical neurons remained normal. The data indicate that ENU administered during embryogenesis has profound and lasting teratological effects on the CNS. (14 refs)

79-0782 Hematological and Histopathological Characteristics of Leukemias Induced by 1-Alkyl-1-nitrosoureas in Donryu Rats. (Eng) Ogiu, T. (Div. Pathology, Biological Safety Res. Center, Natl. Inst. Hygienic Sciences, Kamiyoga 1-18-1, Setagaya-ku, Tokyo 158, Japan). *Gann* 69(6): 781-791; 1978.

The hematologic and histopathologic features of leukemias induced in Donryu rats by 1-methyl-1-nitrosourea (MNU, 100 or 400 ppm in the drinking water), 1-ethyl-1-nitrosourea (ENU, 100 to 400 ppm in the drinking water), 1-propyl-1-nitrosourea (PNU, 150 to 600 ppm in the drinking water, 200 to 800 mg/kg as a single po injection, or 400 mg/kg as a single sc injection), and 1-butyl-1-nitrosourea (BNU, 400 ppm in the drinking water for 5 or 15 wk) were studied. A total of 242 leukemias were induced in 604 rats. The 23 myeloblastic leukemias were characterized by marked anemia, splenomegaly, and hepatomegaly, and the surface of the spleen was nodular in most cases. Survival was longest among the 74 rats with myelocytic leukemia; in this form, the WBC count was high, anemia and hepatosplenomegaly were marked, and leukemic cells invaded the periportal area of the liver. Survival was shortest in the 90 rats with erythroblastic leukemia, which was characterized by hepatomegaly, invasion of the sinusoids by leukemic cells, and adrenal involvement. The 27 cases of lymphoblastic leukemia were characterized by increased WBC count, anemia, slight hepatosplenomegaly, invasion of the hepatic periportal area by leukemic cells, and involvement of the lymphatic tissues. There were also 18 leukemic and 10 unclassified leukemias.

1-Alkyl-1-nitrosourea-induced leukemias in the rat are useful models for various human leukemias. (20 refs)

79-0783 Experimental Production of 'Keratin Pools' in the Rat Forestomach (Meeting Abstract). (Eng) Reibel, J. (Dept. Oral Pathology, Royal Dental Coll., Copenhagen, Denmark); Praetorius, F. *J Dent Res* 58(Special A): 301; 1979. (1 ref)

79-0784 Symposium on the Principles of Radiation Research Applied to Environmental Agents. The Concept of Drug Dose for In Vitro Studies with Chemotherapeutic Agents. (Eng) Wheeler, K. T. (Cancer Center, Div. Radiation Oncology, Univ. Rochester, Rochester, NY, 14642); Levin, V. A.; Deen, D. F. *Radiat Res* 76(3): 441-458; 1978.

Concepts of drug dose are defined, and pharmacokinetic and cell survival data collected from experiments in which rat 9L brain tumor cells were treated in vitro with 1,3-bis(2-chloroethyl)-1-nitrosourea and 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea are used to illustrate the problems and principles involved in adequately assessing the appropriate drug dose in tissue culture. There are two kinds of drug dose analogous to those used in radiation dosimetry: exposure dose is the amount of drug to which cells are exposed in any given time period; and absorbed drug dose is the amount of the biologically active moiety bound to the whole cell or to the specific target in question. Drug dose is dependent on both the stability of the drug and on its concentration in the medium. Practical solutions to the experimental problems raised are presented for many of the situations in which pharmacokinetic data are either unobtainable or unavailable. The concepts illustrated should provide a more uniform framework for performing interpretable in vitro drug experiments. (6 refs)

79-0785 Mutagenicity Tests of Diflubenzuron in the Micronucleus Test in Mice, the L5178Y Mouse Lymphoma Forward Mutation Assay, and the Ames *Salmonella* Reverse Mutation Test. (Eng) MacGregor, J. T. (U.S. Dept. Agriculture, Western Regional Res. Center, Berkeley, CA); Gould, D. H.; Mitchell, A. D.; Sterling, G. P. *Mutat Res* 66(1): 45-53; 1979.

Diflubenzuron, a new commercial pesticide, was tested for mutagenic activity using the micronucleus test in mice, the L5178Y mouse lymphoma forward mutation test at the thymidine kinase locus, and the *Salmonella typhimurium*/microsome reverse mutation assay. No mutagenic effects were seen at concentrations up to 1,860 µg/plate in the *Salmonella* assay, 300 µg/ml in the L5178Y forward mutation test, and 1,500 mg/kg in the micronucleus test. Although the mean incidence of micronucleated polychromatic RBC in the

1,500 mg/kg group was higher than in the control group, the difference was not statistically significant. (25 refs)

79-0786 Sister Chromatid Exchanges in Lymphocyte Cultures of Patients Receiving Chemotherapy for Malignant Disorders. (Eng) Lambert, B. (Dept. Clinical Genetics, Karolinska Hosp., 104 01 Stockholm 60, Sweden); Ringburg, U.; Harper, E.; Lindblad, A. *Cancer Treat Rep* 62(10): 1413-1419; 1978.

The frequency of sister chromatid exchanges (SCE) in the peripheral lymphocytes of 19 patients receiving chemotherapy for different types of neoplastic disease was studied by the fluorescence plus Giemsa technique. The SCE frequency was also determined in 42 healthy subjects. Significantly increased SCE frequencies were noted in six patients 2-7 wk after 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea (CCNU) treatment and in one patient 2 wk after melphalan treatment. In one patient treated with prednimustine and one with 5-(3,3-dimethyl-1-triazeno)imidazole-4-carboximide, high SCE frequencies just below the upper limit of the control range were recorded 1-2 wk after therapy. Nine other patients receiving cytostatic courses of methotrexate, thioTEPA, bleomycin, adriamycin, cyclophosphamide, actinomycin D, 5-fluorouracil, vincristine, and prednimustine showed normal SCE frequencies when studied from 3 days to several weeks after treatment. Full tumor doses of radiotherapy were given to 12 patients, but this treatment did not cause a long-lasting increase in SCE. It is suggested that CCNU and melphalan give rise to DNA lesions that are not easily repaired by cellular enzymes. These long-lived lesions could be important in mutagenesis and in the development of secondary neoplasms. (18 refs)

79-0787 Carcinogenicity and Mutagenicity Testing of Three Isomeric N-Nitroso-N-methylaminopyridines in Rats. (Eng) Preussmann, R. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, D 6900 Heidelberg 1, W. Germany); Habs, M.; Pool, B. L. *J Natl Cancer Inst* 62(1): 153-156; 1979.

The carcinogenicity and mutagenicity of three isomers, 2-, 3-, and 4-N-nitroso-N-methylaminopyridine (2-, 3-, and 4-NMPY), were tested and compared. In the carcinogenicity tests, female BD rats were divided into four groups and given either no treatment or by gavage 2-NMPY [5 mg/kg 1x/wk; median total dose (MTD), 250 mg/kg], 3-NMPY (1 mg/kg 4x/wk; MTD, 328 mg/kg), or 4-NMPY (10 mg/kg 2x/wk; MTD, 1,720 mg/kg). They were observed over their life spans, sacrificed when moribund, and examined for tumor growth. The 2-NMPY-treated animals developed 18 esophageal tumors (12 benign papillomas, 6 carcinomas). In addition, two hemangioendotheliomas of the liver were found that also might be causally related to the treatment. The first tumor was observed on day 268 of treatment, vs day 573 in

controls. 3- and 4-NMPY demonstrated no carcinogenic activity. In the Ames' mutagenicity assay, none of the NMPY's was mutagenic to *Salmonella typhimurium* strains TA98 and TA1537, but high concentrations of 2-NMPY showed mutagenic activity toward strain TA100 when incubated with the S-9 liver microsome fraction isolated from Aroclor 1254-stimulated male Sprague-Dawley rats. These results do not support a postulated reaction mechanism predicting that 3-NMPY would have a reactivity different from the other compounds based on the known difference in chemical reactivity of the three isomeric diazopyridines, potential proximate and ultimate carcinogens. However, this finding does not definitely prove that the diazopyridines are not reactive intermediates. (19 refs)

79-0788 A Study of the Competitive Nitrosations of Pyrrolidine, Ascorbic Acid, Cysteine and *p*-Cresol in a Protein-based Model System. (Eng) Massey, R. C. (Ministry Agriculture, Fisheries and Food, Food Lab. (Colney), Colney Lane, Norwich NR4 7UA, England); Crews, C.; Davies, R.; McWeeny, D. J. *J Sci Food Agric* 29(9): 815-821; 1978.

The effects of competitive C- and S-nitrosations on the formation of nitrosopyrrolidine (NPYR) were determined in a protein-based model system, and the results were compared with those of similar reactions performed in aqueous soln. The protein-based matrix was prepared at a moisture level of 75%, and competitive nitrosations of pyrrolidine with 0.1 M ascorbic acid, cysteine, or *p*-cresol were carried out at 37 C and pH 5.25. The reactions were studied for 1 wk and analyzed daily for NPYR and sodium nitrite. The results of the reactions were similar in the protein-based heterogeneous matrix and in aqueous soln, although nitrite depletion was consistently faster in the former than in the latter. The major factor influencing NPYR formation was the amount of nitrite available for N-nitrosation. Ascorbic acid, cysteine, and *p*-cresol all reduced the formation of NPYR by competing with pyrrolidine for the available nitrite, with ascorbic acid being the most efficient scavenger of free nitrite in both systems. A second pathway of NPYR formation, possibly involving protein (thiol)-bound nitrite, was found for the heterogeneous matrix. The effect of this mechanism became apparent in the presence of an efficient free-nitrite scavenger. (24 refs)

79-0789 Absence of Povidone-Iodine-induced Mutagenicity in Mice and Hamsters. (Eng) Merkle, J. (Dept. Industrial Hygiene and Toxicology, BASF Aktiengesellschaft, D-6700 Ludwigshafen/Rh., W. Germany); Zeller, H. *J Pharm Sci* 68(1): 100-102; 1979.

Povidone-iodine (P-I: iodine as I_3^- ion complex bonded to povidone; available I, 11.2%) was tested for mutagenicity in NMRI mice by the dominant lethal assay (DLA) or the mi-

cronucleus test (MT) and in Chinese hamsters by the bone marrow test (BMT). In the DLA, 20 male mice received 72 mg/kg P-I ip and were mated to 3 females each. The conception rate decreased significantly only during the first week, and the av number of implantations and the mutagenicity index were not affected at any time. In the MT, 10 mice received two 36-mg/kg doses of P-I ip at an interval of 24 hr and were then sacrificed 6 hr later. Bone marrow smears were prepared, and 4,000 normochromatic and 2,000 polychromatic RBC were examined/animal. Although there was a slight increase in polychromatic RBC containing micronuclei, this increase was within the normal range. In the BMT, groups of 12 animals received single P-I doses of 38.3 or 82.5 mg/kg ip or five daily ip injections of 38.3 mg/kg on 5 successive days. There was no difference from controls in the percentage or type of aberrant metaphases seen when the substance was administered singly or repeatedly. None of these three tests revealed any evidence of a mutagenic effect for P-I. (6 refs)

79-0790 Spin Trapping of Free Radicals Produced from Nitrosoamine Carcinogens. (Eng) Floyd, R. A. (Biomembrane Res. Lab., Oklahoma Medical Res. Foundation, 825 Northeast Thirteenth St., Oklahoma City, OK, 73104); Soong, L. M.; Stuart, M. A.; Reigh, D. L. *Photochem Photobiol* 28(4/5): 857-862; 1978.

The spin trap 5,5-dimethylpyrroline-1-oxide (DMPO) was utilized to investigate nitrosoamine carcinogens by electron spin resonance spectroscopy. Incubation of 10-20 mM 1-nitrosopiperidine with rat liver microsomes or nuclei at 37 C in the presence of DMPO (20 mM) yielded a trapped hydroxyl free radical and a spin-trapped free radical of the carcinogen whose structure is unknown. Oxygen was required to produce the trapped hydroxyl radical, but formation of the nitrosoamine radical was enhanced in the absence of oxygen. Cyanide (0.5 mM) or α -tocopherol acetate (1 mM) reduced the amount of nitrosoamine trapped radical in the reaction, whereas preheating microsomes at 70 C for 10 min enhanced its formation. Dimethylnitrosamine, diethylnitrosamine, and 1-nitrosopyrroline yielded a similar pattern of trapping two radicals when studied in this reaction, although the structure of the trapped carcinogen radical obviously differed. The amount of radical produced was not proportional to the cytochrome P450 content. It is suggested that the unknown free radical of the trapped nitrosoamine could be the hydroxy alkyl free radical. (25 refs)

79-0791 Ritalin, Benzedrine and Dexedrine Do Not Transform F1706 Rat Cells. (Eng) Price, P. J. (Center Disease Control, Building 1, Room 3237, 1600 Clifton Rd, N.E., Atlanta, GA); Gregory, E. A.; Skeen, P. C. *Cancer Lett* 5(6): 345-349; 1978.

Ritalin (methylphenidate hydrochloride), Benzedrine (am-

phetamine sulfate), and Dexedrine (dextroamphetamine sulfate), frequently prescribed CNS stimulants, were examined for oncogenicity using a serial line of Fischer rat embryo cells. This line was previously shown to be a sensitive and accurate indicator of chemicals carcinogenic for rodents. In the transformation assay, rat embryo cells were incubated with 20 $\mu\text{g}/\text{ml}$ (max nontoxic dose) or 40 $\mu\text{g}/\text{ml}$ (LD_{50}) of one of the three drugs. Tumorigenicity was determined by injection of treated cells into newborn Fischer rats (5×10^5 cells sc). 3-Methylcholanthrene (3-MC: 0.2 $\mu\text{g}/\text{ml}$) was a positive control. All the 3-MC-treated cultures developed transformed foci within four subcultures after removal of the chemical. Cultures treated with one of the three drugs or acetone were phenotypically normal at the end of the experiment (after 8 subcultures) and produced no foci in agar. Only the 3-MC-treated cultures were tumorigenic in the newborn rats. These results are reported to add to the data base necessary for determining the relevancy of in vitro mammalian cell assays, and not to indicate that the drugs are safe for humans. (6 refs)

79-0792 Levels of Glutathione, Glutathione Reductase and Glutathione S-Transferase Activities in Rat Lung and Liver. (Eng) Moron, M. S. (Dept. Biochemistry, Arrhenius Lab., Univ. Stockholm, S-106 91 Stockholm, Sweden); DePierre, J. W.; Mannervik, B. *Biochim Biophys Acta* 582(1): 67-78; 1979.

Levels of glutathione (GSH), glutathione reductase, and glutathione S-transferase activities in the lung and liver of male Sprague-Dawley rats were investigated. After the lung was perfused to remove contaminating blood, an apparent concentration of 2 mM GSH was detected in this organ; the liver contained five times as much GSH. A single liver cell contained 11 times as much GSH as a lung cell. Rat lung tissue contained very little GSH disulfide (0.060 mM); rat liver tissue has been reported to contain very low levels of this substance (0%-8% of the GSH concentration). There were no significant differences in the levels of reduced GSH in lung or liver of rats pretreated with phenobarbital (80 mg/kg 1x/day ip for 5 days) or methylcholanthrene (20 mg/kg 1x/day ip on 5, 3, and 1 day before killing). The activities of GSH reductase and GSH S-transferase assayed with four different substrates were 5-60 times lower in lung than in liver. The relative levels of GSH and GSH S-transferase activities in the liver and lung may be an important factor in the relative susceptibility of these organs to the toxic and carcinogenic effects of xenobiotics and their metabolites. (38 refs)

79-0793 Induction of Mixed-Function Oxidases in Mouse Liver by Psoralens. (Eng) Mandula, B. B. (Dept. Dermatology, Massachusetts General Hosp., Boston, MA, 02114); Pathak, M. A.; Nakayama, Y.; Davidson, S. J. *Br J Dermatol* 99(6): 687-692; 1978.

The induction of mixed-function oxidases in mouse liver was determined following po or ip treatment of male CD-1 mice with 100 mg/kg 8-methoxypsoralen (8-MOP), 4,5',8-trimethylpsoralen (TMeP), psoralen, or phenobarbital. 8-MOP or phenobarbital induced a 2.5- to 3-fold increase in p-nitroanisole-O-demethylase (pND) activity in mouse liver homogenates. 8-MOP also increased the arylhydrocarbon hydroxylase (AHH) activity of the homogenates, whereas TMeP and psoralen did not increase either pND or AHH activity. Similar results were obtained with liver microsomes. The pND and AHH activities increased with increasing 8-MOP dose between 25 and 100 mg/kg. Enzyme induction was barely detected after treatment with 10 mg/kg 8-MOP. These results may have relevance in understanding the clinical differences in skin photosensitizing activity and the photochemotherapeutic effectiveness of the psoralens in diseases such as psoriasis and vitiligo. 79-0794 Demonstration of Mutagenicity with the Ames Salmonella/Microsome Assay. (Hun) Ferencz, A. (Komaron megyei Kozegeszsegugyi-Jarvanyugyi Alomas, Tatabanya, Hungary); Kiss, K.; Pinter, A.; Nadasdi, L.; Bornemisza, E.; Csinady, L. *Egeszsegudomány* 22(4): 379-387; 1978.

Experience with the Ames *Salmonella typhimurium*/microsome mutagenicity assay is reviewed. *Salmonella* strains TA1535, TA1537, TA1538, TA98, and TA100 were found to retain their genetic characteristics in the assay. Both the filter disk and the plate were suitable for detecting the mutagenicity of streptozotocin. The former is recommended for screening potentially mutagenic environmental chemicals and the latter is recommended for a more precise characterization of a mutagen. (16 refs)

79-0795 Ultrastructural Nuclear Changes in Human Lymphocytes Following Arabinosylcytosine Treatment In Vitro. (Eng) Conforti, A. (Istituto di Patologia Generale, Policlinico Umberto I, Viale Regina Elena no. 324, I-10000 Rome, Italy); Albani, L. M.; Modesti, A.; Leopardi, S.; Felici, L. *Virchows Arch Cell Pathol* 28(4): 301-308; 1978.

Treatment of synchronous normal human lymphocytes during the G_1 phase with 0.5 mg/ml cytosine arabinoside produced alterations in the nuclear envelope that closely resembled the malignancy-associated changes seen in human leukemic cells. The changes which occurred in an av of 5.4/1,000 cells consisted of blebs, pockets, filamentous invaginations, and projections containing nuclear or cytoplasmic material, and they were not seen in untreated cells. (27 refs)

79-0796 Complex Formation Between Pyrene and the Nucleotides GMP, CMP, TMP and AMP.

(Eng) Lianos, P. (Dept. Physics, Univ. Tennessee, Knoxville, TN, 37916); Georgiou, S. *Photochem Photobiol* 29(1): 13-21; 1979.

A study of the optical properties of the complexes formed between pyrene and nucleotides revealed that pyrene forms ground and excited electronic state complexes of 1:1 stoichiometry with guanosine, cytidine, and thymidine 5'-phosphate disodium salts and AMP. Ground and excited state association constants are presented. Partial transfer of charge from pyrene to nucleotide may play a role in complex formation. (24 refs)

79-0797 Synthesis and Properties of O⁶-Methyldeoxyguanylic Acid and Its Copolymers with Deoxycytidylic Acid. (Eng) Mehta, J. R. (Dept. Pharmacology and Experimental Therapeutics, Albany Medical Coll. Union Univ., Albany, NY, 12208); Ludlum, D. B. *Biochim Biophys Acta* 521(2): 770-778; 1978.

O⁶-Methyldeoxyguanosine triphosphate (m⁶dGTP) was synthesized from deoxyguanosine first protected by acetylation of the sugar hydroxyls and then chlorinated in the 6-position with POCl₃. The product was converted to O⁶-methyldeoxyguanosine and phosphorylated in the 5' position. Monophosphate was converted to the triphosphate and copolymerized with deoxycytosine triphosphate by terminal deoxynucleotidyl transferase. The resulting template, which contained O⁶-methylguanine, was tested for its ability to direct RNA synthesis by bacterial RNA polymerase. O⁶-Methylguanine led to the misincorporation of uridine monophosphate in the product polymer, supporting the hypothesis that O⁶-methylguanine is a promutagenic base. (20 refs)

79-0798 Effect of Misonidazole (Ro-07-0582) on the Incidence of Micronuclei in Irradiated Ehrlich Tumour Ascites Cells. (Eng) Olinici, C. D. (Inst. Oncology, Republicii 34-36, R-3400 Cluj-Napoca, Romania); Mustea, I. *Int J Radiat Biol* 34(6): 589-593; 1978.

The effect of misonidazole (MNZ), a potent hypoxic radiosensitizing chemical, on the incidence of micronuclei was studied in irradiated Ehrlich ascites cells in NMRI male mice. The animals received MNZ (0.5 mg/g ip) 30 min prior to irradiation with 100, 200, or 400 R. Animals in each group were killed 24, 48, and 72 hr after irradiation, and the frequency of micronuclei in ascites cells was calculated after 2,000 cells were scored in each animal. Irradiation induced a dose-dependent increase in the frequency of micronuclei. A further enhancement of micronuclei formation was observed in the groups pretreated with MNZ. The largest number of micronuclei was reached 72 hr after irradiation in control groups irradiated with 100 and 200 R and in the MNZ-treated group irradiated with 100 R, and 48 hr after irradiation in the control group irradiated with 400 R and

in the MNZ-treated group irradiated with 200 and 400 R. These results show that MNZ pretreatment increased the incidence of micronuclei in irradiated tumor cells, and they suggest the possibility of using the micronucleus assay for screening substances with a radiosensitizing potential. (15 refs)

79-0799 The Effect of Several Lymphocytotoxic Agents on Murine Leukemogenesis. (Eng) Menahan, L. A. (Dept. Pharmacology, Medical Coll. Wisconsin, Milwaukee, WI, 53233); Kemp, R. G. *Life Sci* 23(16): 1687-1692; 1978.

The actions of the lymphocytotoxic agents cortisone (CTS), 5'-azathioprine (AZT), and 5-(3,3-dimethyl-1-triazeno)imidazole-4-carboximide (DTIC) on leukemogenesis in male AKR/J and male ARS HA/1CR (Swiss albino) mice were compared. CTS (1 mg) was injected sc for 3 consecutive days on two occasions 1 mo apart; AZT (17 3-mg doses) was injected into the thigh over a period of 8 wk (3 doses/wk for 1 mo; 2 doses for 1 wk; 1 dose/wk for 3 wk), and DTIC was injected once ip into both strains in doses ranging from 240 to 530 mg/kg. Both CTS and AZT prolonged survival in AKR/J mice, whereas DTIC induced lymphomas after a 70-day lag period in >90% of both AKR/J and Swiss albino mice. All DTIC-treated mice had grossly enlarged thymuses and most had enlarged spleens. In short term experiments, all three agents reduced the population of medium-sized lymphocytes in the thymus within 48 hr, and CTS and DTIC also led to a reduction in spleen wt. The results of the DTIC experiment indicate that it could be a model for studying critical events in the preleukemic state. (7 refs)

79-0800 Acute Myelomonocytic Leukemia Following a Chemotherapeutic Regimen for Metastatic Sarcoma. (Eng) Youness, E. (Dept. Lab. Medicine, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030); Dosik, G.; Benjamin, R. S.; Trujillo, J. M. *Cancer Treat Rep* 62(10): 1513-1516; 1978.

A 64-yr-old woman developed acute myelomonocytic leukemia (AML) in June 1977, 18 mo after treatment with a protocol of cyclophosphamide, vincristine, adriamycin, and 5-(3,3-dimethyl-1-triazeno)imidazole-4-carboxamide (the CyVADIC regimen) for a metastatic sarcoma. The patient had had no prior history of radiation. In 1973, an adenocarcinoma (Grade I) with superficial myometrial invasion and a hemorrhagic leiomyoma were identified upon abdominal hysterectomy and bilateral salpingo-oophorectomy. In December, 1975, the patient was diagnosed as having metastatic sarcoma suggestive of leiomyosarcoma after a left thoracotomy was performed for multiple pulmonary nodules. Chemotherapy was initiated at this time. In March 1976, she was discharged in partial remission, but in November the

pulmonary nodules had increased in size. Substitution of actinomycin D for adriamycin in February 1977 was not helpful, and monocytosis was noted in a peripheral blood smear at this time. In June 1977, she was treated with cis-dichlorodiammineplatinum (II) to control metastatic disease. The clot section of a bone marrow aspiration revealed marrow particles with a cellularity of 70% and sheets of immature myelomonocytic cells. Results of bone marrow smear, special staining, and complete blood count led to the diagnosis of AML. This is the first known case of leukemia in > 400 trials of the CyVADIC regimen. (31 refs)

79-0801 Development of an Intestinal Cell Culture Method to Study Dietary Effects of Intestinal Mutagens. (Eng) Lee, W. Y. (Michigan State Univ., East Lansing, MI, 48832). *Diss Abstr Int B* 39(7): 3248B; 1979. (no refs)

79-0802 Repair of O⁶-Methylguanine in Adapted *Escherichia coli*. (Eng) Schendel, P. F. (Imperial Cancer Res. Fund, Mill Hill Labs., Burtonhole Lane, London, NW7 1AD, England). *Proc Natl Acad Sci USA* 75(12): 6017-6020; 1978.

The chromatographic spectra of alkylated purines found in adapted and control *Escherichia coli* cells exposed to N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) were analyzed. [The cells were adapted by previous exposure to sublethal concentrations of MNNG (0.05 and 0.5 µg/ml).] During exposure to 5 or 10 µg/ml MNNG, the adapted cells accumulated substantially less O⁶-methylguanine (OMG) in their DNA than control cells; accumulations of 7-methylguanine and 3-methyladenine were similar. The adapted cells reduced the accumulation of OMG in their DNA by reducing the O⁶ methylation of guanine and by rapidly removing the OMG when it did form. However, the repair component of the adaptive response was limited and it ceased to function if the amount of methylation became too great. When this happened, OMG started to accumulate, and the cells began to develop mutations at a rate directly proportional to their rate of OMG accumulation. The data support the idea that the O⁶ methylation of guanine accounts for most MNNG-induced mutagenesis. (20 refs)

79-0803 Modification of Rat Liver Chromatin by N-Methyl-N'-nitro-N-nitrosoguanidine or N-Ethyl-N'-nitro-N-nitrosoguanidine and Template Activity for RNA Synthesis by *Escherichia coli* RNA Polymerase after Reconstitution. (Eng) Yoda, K. (Div. Biochemistry, Chiba Cancer Center Res. Inst., 666-2, Nitona-Cho, Chiba 280, Japan); Sakiyama, S.; Fujimura, S. *Biochim Biophys Acta* 521(2): 677-688; 1978.

The binding of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) and N-ethyl-N'-nitro-N-nitrosoguanidine (ENNG) to the DNA, histones, and nonhistone chromosomal proteins (NHCP) of Donryu rat liver chromatin was studied. The binding of MNNG and ENNG to histones or NHCP increased linearly with time up to 6 hr. MNNG showed greater binding than ENNG, and the binding of the guanidino moiety of either compound was greater than that of the corresponding alkyl moiety. The binding of both compounds to DNA, however, was very low. In order to compare the effect of modification of each component of chromatin by MNNG or ENNG, each component modified separately was reconstituted with the two other intact components. Then, ³H-uridine monophosphate incorporation into acid-insoluble material was measured using *Escherichia coli* RNA polymerase. The template activity of whole chromatin for RNA synthesis was similar to that of untreated reconstituted chromatin. However, the template activity of reconstituted chromatin containing MNNG-modified histones was increased about 10-fold and the template activity of reconstituted chromatin containing ENNG-modified histones was increased about 5-fold. Modification of the NHCP or DNA of reconstituted chromatin had no effect on template activity. The template activity of whole chromatin treated with MNNG or ENNG increased approx two-fold over that of untreated whole chromatin. (33 refs)

79-0804 Inactivation of N-Methyl-N'-nitro-N-nitrosoguanidine in the Ames *Salmonella*/Microsome Test. (Eng) Gentile, J. M. (Dept. Biology, Hope Coll., Holland, MI, 49423); Overton, L. K.; Schubert, J. *Naturwissenschaften* 65(12): 659-660; 1978.

The mutagenic deactivation of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) by various fortified rat liver homogenate (S-9) preparations in the Ames *Salmonella* test was investigated. The mutagenicity of MNNG decreased proportionately with the milligrams of protein of S-9 added per plate. However, when NADPH was omitted from the reaction mixture or when the *Salmonella* were incubated with bovine serum albumin or various maize tissue homogenates, no decrease in MNNG mutagenic activity was observed. These data indicate that an NADPH-dependent enzyme(s) in standard S-9 preparations inactivates MNNG. This was confirmed by the observation that S-9 preparations in which the metabolizing enzymes had been inactivated by heat, pH variation, and treatment with 4-chloromercuribenzoic acid failed to inactivate MNNG. The promutagens aflatoxin B₁ and 2-anthramine required the addition of S-9 before their mutagenic activity was observed. Ethyl methane sulfonate and streptozotocin were unaffected by the addition of S-9, but N-ethyl-N'-nitro-N-nitrosoguanidine was deactivated by this preparation. Since the mutagenicity of a known and powerful carcinogen such as MNNG can be modified or eliminated by simplistic means in standard mutation assays, it may be premature to accept routinely the results of mutagenic-carcinogenic potency correlations. (16 refs)

79-0805 Formation of Methylnitrosocyanamide from Methylguanidine and Sodium Nitrite in Simulated Gastric Juice and in Stomachs of Rats: Quantitative Estimation by a Mutagenicity Assay. (Eng) Ishizawa, M. (Dept. Hygiene, Faculty Medicine, Kyushu Univ., Higashi-ku, Fukuoka 812, Japan); Utsunomiya, T.; Kinoshita, N.; Endo, H. *J Natl Cancer Inst* 62(1): 71-77; 1979.

The formation of methylnitrosocyanamide (MNC), a carcinogenic N-nitroso compound, from methylguanidine (MG) and NaNO_2 in simulated gastric juice (SGJ) and in the stomachs of male Wistar rats was quantitatively investigated. In the *Salmonella typhimurium* reverse mutation assay using strain TA1535, MNC formation increased linearly for about 40-60 min after the incubation of MG with NaNO_2 in SGJ. Thereafter, however, it decreased rapidly. The initial rate of MNC formation was directly proportional to the initial molar ratio of MG to NaNO_2 , but the yields of MNC depended only on the amount of MG added and were fairly constant (0.3%-0.5% of the initial MG). MNC did not form at a pH above 2.5 or in the presence of 2% casein in SGJ at pH 1.2. It decomposed rapidly in SGJ at pH 1.2 with a half-life of approx 2 min, whereas it was stable in phosphate buffer at pH 7.0. Following concurrent administration of MG and NaNO_2 via stomach tube, MNC formation was detected in the pylorus-ligated stomachs of rats preconditioned with a casein-free dextrin diet but not in those of rats preconditioned with a casein-containing or synthetic diet. The yields of MNC observed 40-60 min after administration of reactants ranged from 0.02% to 0.05% of the initial MG. The possible environmental significance of MNC formation in vivo is considered. (24 refs)

79-0806 Carcinogenic Effect of a Guanidine Pesticide Administered with Sodium Nitrite on Adult Mice and on the Offspring after Prenatal Exposure. (Eng) Borzsonyi, M. (Natl. Inst. Hygiene, H-1966 Budapest, Hungary); Pinter, A.; Surjan, A.; Torok, G. *Cancer Lett* 5(2): 107-113; 1978.

The carcinogenicity of the fungicide dodecylguanidine acetate (DGA, dodine) was studied in pregnant Swiss/Leiden mice and their offspring. On gestation days 15-21, the females were given 6 or 40 mg/kg DGA and 10 mg/kg sodium nitrite intragastrically plus 0.1% sodium nitrite in the drinking water. Controls received DGA or sodium nitrite alone or were untreated. Most of the resulting tumors were lymphosarcomas, and the incidence in the female parents given 6 and 40 mg/kg DGA was 47.1% and 52.9%, respectively. The first tumor appeared 4 mo after delivery. The incidence in the offspring was 22.9% and 50% in males and 32.6% and 43.8% in females at the two respective doses. Thus, the carcinogenicity of DGA was dose-dependent. The first tumors appeared at 6-7 mo. The spontaneous incidence of lymphosarcomas in untreated controls was approx 1% by 10 mo. DGA alone and sodium nitrite alone had no effect on cancer incidence. A few lung adenomas were seen in the experimen-

tal animals. The high incidence of lymphosarcomas in the adult females could be due to the increased levels of estrogens during pregnancy. A- and C-type RNA virus particles were found in the tumor cells by electron microscopy. (20 refs)

79-0807 Tumor Induction in the Glandular Stomach of Rats after Oral Administration of a Single or a Few Doses of N-Methyl-N'-nitro-N-nitrosoguanidine During the Newborn Period. (Eng) Sumi, Y. (Lab. Germfree Life Res., Nagoya Univ. Sch. Medicine, 65 Tsurumai-cho, Showa-ku, Nagoya 466, Japan); Miyakawa, M. *Gann* 69(6): 805-812; 1978.

The carcinogenicity of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) in newborn male and female Wistar rats was studied. MNNG was given po (using a catheter technique) as a single dose (100 μg) to animals less than 24-hr-old (Group 1) and as 3 consecutive daily doses (150 μg each) to rats aged 2 to 5 days (Group 2). Survival to 30 days after the first dose was high and the carcinogen had no effect on body wt. Adenocarcinomas of the fundic and pyloric stomach were found in 5/19 Group 1 rats and 15/33 Group 2 rats surviving until day 473 after the first dose. The tumors frequently invaded the serosa, and metastases to other portions of the digestive system were observed in two animals. Leiomyosarcomas were found in one Group 1 rat and three Group 2 rats, carcinosarcomas were found in one animal from each group, and a squamous cell carcinoma was found in one Group 2 rat. In addition to these tumors, all of which occurred in the glandular stomach, two adenomas of the liver and two adenocarcinomas of the duodenum were observed, as were several benign tumors. (16 refs)

79-0808 Synthesis of 4-(N-Hydroxy-N-methylamino)quinoline 1-Oxide and Its Carcinogenic Activity on Mice. (Eng) Kawazoe, Y. (Faculty Pharmaceutical Sciences, Nagoya City Univ., Tanabe-dori, Mizuho-ku, Nagoya 467, Japan); Ogawa, O.; Takahashi, K.; Sawanishi, H.; Ito, N. *Gann* 69(6): 835-837; 1978.

The synthesis and carcinogenicity of 4-(N-hydroxy-N-methylamino)-quinoline 1-oxide (N-Me-4-HAQO) were investigated. The compound, which consists of the quinoline 1-oxide moiety of 4-nitroquinoline 1-oxide and the N-hydroxy-N-methylamino group of N-hydroxy-N-monomethylaminoazobenzene, was synthesized by treatment of 4-chloroquinoline 1-oxide with N-methylhydroxylamine. The compound was fairly stable. Following 10 weekly sc injections (0.15 or 1.5 mg each) into 5-wk-old male ddY mice, the following palpable tumors were induced at the site of injection within 105 to 390 days: fibrosarcomas in 13 of 22 animals, an unclassified sarcoma in 1 animal, and a squamous cell papilloma in 1 animal. (9 refs)

- 79-0809 Ethoxyquin Feeding to Rats Increases Liver Microsome-catalyzed Formation of Benzo(a)pyrene Diol Epoxide-DNA Adduct.** (Eng) Kahl, R. (Dept. Pharmacology, Univ. Mainz, Obere Zahlbacher Strasse 67, D-6500 Mainz, W. Germany); Deckers-Schmelzle, B.; Klaus, E. *Biochem Biophys Res Commun* 85(3): 938-945; 1978.

The effect of feeding ethoxyquin (EQ) on the liver microsome-catalyzed formation of benzo(a)pyrene (BP) diol epoxide-DNA adducts was studied in vitro. The microsomes were prepared from male Sprague-Dawley rats that had received 0.5% EQ in the diet for 14 days. Calf thymus DNA was incubated with liver microsomes in the presence of 6 μ M ³H-BP. Sephadex LH 20 chromatography revealed that the formation of the benzo(a)pyrene 7,8-diol-9,10-epoxide-DNA nucleoside adduct was increased threefold by feeding 0.5% EQ. Microsomal epoxide hydratase activity was also enhanced by a factor of three, but aryl hydrocarbon hydroxylase activity was not induced. A threefold increase in the diol epoxide-DNA adduct was also found when liver microsomes from animals treated with EQ plus 3-methylcholanthrene (3-MC) were used, compared with microsomes from animals treated with 3-MC only. The main chromatographic peak formed by microsomes from 3-MC-treated rats, which contained DNA adducts of secondary BP phenol metabolites, was reduced when the animals had received EQ. Increased formation of the diol epoxide adduct was not an expected finding for a substance that reportedly reduces tumor induction by BP. However, the reduction in the formation of DNA adducts of secondary BP phenol metabolites may be related to the protective action of EQ. (25 refs)

- 79-0810 Effects of Various Chemical Agents on Sister Chromatid Exchanges, Chromosome Aberrations, and DNA Repair in Normal and Abnormal Human Lymphoid Cell Lines.** (Eng) Shiraishi, Y. (Dept. Anatomy, Kochi Medical Univ., Kochi 780, Japan); Sandberg, A. A. *J Natl Cancer Inst* 62(1): 27-35; 1979.

The effects of various chemical agents on cell lethality, chromosome aberrations, sister chromatid exchanges (SCE), and DNA repair were studied using cell lines derived from normal human male lymphocytes and from a patient with chronic lymphocytic leukemia (CML, line SN1029). Compared with the normal cells, SN1029 cells were more sensitive to the lethal effects of 4-nitroquinoline 1-oxide (4-NQO), methyl methanesulfonate (MMS), ethyl methanesulfonate (EMS), mitomycin C (MMC), daunomycin (DM), bleomycin, and cytosine arabinoside, but not to the lethal effects of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG). MMC also increased the frequency of SCE in SN1029 cells but did not increase the frequency of chromosome breakages. The other agents did not increase the SCE frequency, although they did increase chromosome aberrations. Unscheduled DNA synthesis (USD) was examined following UV irradiation and chemical treatment for 90 min at 6.0 μ g/ml (experiment 1) or for 48 hr at 0.003-6.0 μ g/ml (experiment 2). USD

occurred after treatment with 4-NQO, EMS and MNNG but not after treatment with MMC in experiment 1. USD did not occur after any treatment in experiment 2. The repair level did not differ between normal and SN1029 cells exposed to UV-radiation and 3-NQO, EMS, or MNNG. The results indicate the SCE and excision repair are not closely linked and that the SCE sensitivity and cell death of the CLL line are independent of the quantitative capacity for excision repair. - 79-0811 Kinetics of DNA Repair Synthesis in Human Fibroblasts Induced by Chemical Carcinogens and Ultraviolet Light (Meeting Abstract).** (Eng) Levinson, J. W. (Michigan State Univ., East Lansing, MI, 48824); Maher, V. M.; McCormick, J. J. *Biophys J* 25(2, part 2): 154a; 1979. (no refs)

- 79-0812 Metabolic Pathways of the N-Substituted Naphthalenes: Their Relationship to Mutagenicity and Carcinogenicity (Meeting Abstract).** (Eng) Benkendorf, C. A. (Univ. Michigan, Ann Arbor, MI, 48104). *Diss Abstr Int B* 39(6): 2723; 1978. (1 ref)

- 79-0813 Polarographic Determination of Some Carcinogenic Aminoazobenzenes.** (Eng) Carruthers, C. (Orchard Park Lab., Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263). *Mikrochim Acta* 2(5/6): 463-472; 1978.

Polarography was applied to the quantitative analysis of 14 carcinogenic and noncarcinogenic aminoazobenzenes in ethanol-buffer solns. Plots of diffusion current vs concentration gave straight lines with different slopes, so that this method can be used for the quantitative analysis of any of the compounds tested. As the pH increased, the diffusion current decreased. Only N'-methyl-4'-amino-N-methyl-4-aminoazobenzene could be determined in the presence of any of the ring-substituted aminoazobenzenes on the basis of half-wave potential. There was no apparent relationship between structure and half-wave potential or between half-wave potential and carcinogenicity of the ring-substituted aminoazobenzenes. (17 refs)

- 79-0814 An Evaluation of a Polyurethane for Use as a Medical Grade Plastic.** (Eng) Darby, T. D. (Travenol Labs., Inc., Morton Grove, IL, 60053); Johnson, H. J.; Northup, S. J. *Toxicol Appl Pharmacol* 46(2): 449-453; 1978.

The mutagenic potential of 4,4'-methylenedianiline (MDA), an aromatic amine analog of 4,4'-diphenylmethane diiso-

cyanate (MDI), was tested in the Ames' mutagenicity assay using *Salmonella typhimurium* test strains TA98, TA100, TA1535, TA1537, and TA1538. MDI is a constituent of a new polyurethane developed for use as blood bag material, and it yields MDA when it is autoclaved in aqueous soln for 2 or 5 hr. MDA (50 or 150 μ g) was incubated with the bacteria in the presence or absence of an S-9 liver microsome fraction from Sprague-Dawley rats. MDA was mutagenic to strains TA100 and TA98 in the presence of the S-9 mix (the number of revertants was more than double that seen in control plates), and the effect was dose-dependent. Thus, it was decided that the specific aromatic polyurethane did not have a benefit/risk ratio comparable to those established for existing blood bag materials. (11 refs)

79-0815 Testing of Twenty-one Environmental Aromatic Amines or Derivatives for Long-term Toxicity or Carcinogenicity. (Eng) Weisburger, E. K. (Carcinogen Metabolism and Toxicology Branch, NCI, Bethesda, MD, 20014); Russfield, A. B.; Weisburger, J. H.; Boger, E.; Van Dongen, C. G.; Chu, K. C. *J Environ Pathol Toxicol* 2(2): 325-356; 1978.

Twenty-one aromatic amines and derivatives were tested for long-term toxicity following dietary administration to male Charles River rats and male and female HaM/ICR mice. 2,4-Toluenediamine, o-phenylenediamine, o-toluidine, 2,4,6-trimethylaniline, 2,4,5-trimethylaniline, 2,5-xylidine, and 1-chloro-2-nitrobenzene produced tumors in all three animal models, whereas p-toluidine, 4-chloro-o-toluidine, and 1-chloro-4-nitrobenzene were carcinogenic only in the mice. 4-Chloro-4'-aminodiphenyl ether affected the rats and female mice, but there was no consistent dose response. 2,5-Dimethoxy-4'-aminostilbene was carcinogenic in the rats but had only a questionable action in male mice; it was noncarcinogenic in female mice. 3,3',4,4'-tetraaminobiphenyl was carcinogenic in male mice, but its effect in the rats was borderline; it was noncarcinogenic in female mice. 2,4,6-Trichloroaniline was carcinogenic in male mice but not in rats, tetrafluoro-m-phenylenediamine was somewhat less carcinogenic in male mice and noncarcinogenic in the rats and in female mice, and m-toluidine showed only questionable activity (in male mice). 2,4-Xylidine was carcinogenic in female mice but not male mice or rats; 2,4,6-trimethylaniline caused hepatic cirrhosis in rats only and no tumors in rats or mice. m-Phenylenediamine, 2,4-dinitrochlorobenzene benzoquinamine, and dicyclopentadiene dioxide were inactive in both species. (31 refs)

79-0816 Air Sampling and Analytical Method for 4,4'-Methylenebis(2-chloroaniline). (Eng) Rapaport, S. M. (Sch. Public Health, Univ. California, Berkeley, CA, 94720); Morales, R. *Anal Chem* 51(1): 19-23; 1979.

A sampling/analytical method for determining airborne exposures of individuals to the carcinogen 4,4'-me-

thylenebis(2-chloroaniline) (MOCA) was developed. The sampler uses a filter to collect particulate MOCA and a bed of silica gel to remove the vapors. MOCA is analyzed by a high-pressure liquid chromatography equipped with a UV photometer (254 nanometers). The method allows quantitation of 3 nanograms of MOCA corresponding to 0.15 μ g/sample. (14 refs)

79-0817 Lifespan Carcinogenicity Studies with Hexachlorophene in Mice and Rats. (Eng) Rudali, G. (Equipe de Recherche 190 du C.N.R.S., Fondation Curie, 26 rue d'Ulm, Paris, France); Assa, R. *Cancer Lett* 5(6): 325-332; 1978.

Hexachlorophene (HCP) was tested for carcinogenicity in lifetime feeding studies in male Sprague-Dawley rats fed a protein- and vitamin-deficient diet and in C57Bl and XVII/G mice fed a complete diet. Rats received a daily HCP dose of approx 1.5 mg/rat and mice, approx 0.45 mg/mouse. Lifespan and survival rates were similar in treated and control groups. No significant carcinogenic effects were observed in rats or mice during the 2-yr study period. In XVII/G mice injected at birth (0.05, 0.05, and 0.1 mg HCP/animal sc on days 1, 2, and 8 of life) or receiving HCP in the mother's milk (0.5 mg HCP/nursing animal for 20 days), the incidence of tumors was not statistically increased. One of the males injected at birth developed a nonmalignant hepatoma, and three of the males that received HCP during nursing developed liver tumors, one of which was an adenocarcinoma. None of the untreated mice developed hepatomas. No carcinogenic effect was observed in (C57Bl x C3H) F₁ hybrid mice that received HCP transplacentally (0.5 mg/pregnant mouse on gestation days 16 and 18). It is concluded that HCP is not carcinogenic for rodents. (16 refs)

79-0818 Carcinogenesis of Hexachlorobenzene in Mice. (Eng) Cabral, J. R. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE, 68105); Mollner, T.; Raitano, F.; Shubik, P. *Int J Cancer* 23(1): 47-51; 1979.

Long-term experiments on the carcinogenicity of hexachlorobenzene (HCB) were carried out in outbred Swiss mice. The animals received HCB at 50 ppm in the diet for 120 wk, 100 ppm for 106 wk, 200 ppm for 101 wk, or 300 ppm for 15 wk. Survival was reduced after the 30th wk in mice given 200 and 300 ppm HCB. The incidence of liver-cell tumors was increased in mice fed more than 50 ppm; the percentages of liver tumor-bearing animals in the control, 50-ppm, 100-ppm, 200-ppm, and 300-ppm groups was 0%, 0%, 10%, 25%, and 5%, respectively. Most liver-cell tumors were first observed between wk 50 and 99. Lymphoma incidence was 35% in controls, 48% in animals fed 50 ppm HCB, 21% in those fed 100 ppm, 11% in those fed 200 ppm, and 25% in those fed 300 ppm. The low tumor incidence in mice fed HCB, particu-

larly those fed 200 ppm, probably reflects the fact that these animals had the shortest life span; the av time of death for mice with lymphomas following treatment with 200 ppm HCB was 56 wk, in comparison with 86 wk in controls. The incidence of lung tumors was higher in controls than in the treated groups, but the multiplicity (nodules/mouse) was approximately the same in all groups. The results show that concentrations of 100 ppm HCB or more in the diet induce liver-cell tumors in mice, which confirms the results of previous studies. (14 refs)

- 79-0819 Determination of Benzene Concentrations in Work Areas by Gas Chromatography.** (Rum) Matei, L. (Institutul de Igiena si sanatate publica, Bucharest, Romania); Pasat, V. *Rev Ig (Ig)* 27(3): 285-288; 1978.

A gas chromatographic method for the separation and quantitative determination of benzene in work areas is described. Benzene is adsorbed from the air on activated carbon. The method is simple, rapid, specific, and highly sensitive (1 nanogram/ μ l). (30 refs)

- 79-0820 Determination of Benzene Level in Blood.** (Rus) Pinigina, I. A. (A. N. Sysin Inst. General and Communal Hygiene, Moscow, USSR); Mal'tseva, N. M. *Gig Sanit* (12): 67-71; 1978.

Disadvantages of the analysis of biologic specimens by head space chromatography are discussed briefly, and a modified method of determining microquantities of benzene in the blood of experimental animals is described. The sensitivity of the assay was 0.01 μ g/0.5 ml of blood; the duration of analysis ranged from 10 to 15 min. (6 refs)

- 79-0821 Contamination from Feeding Volatile Test Chemicals.** (Eng) Sansone, E. B. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Losikoff, A. M. *Toxicol Appl Pharmacol* 46(3): 703-708; 1978.

Experiments demonstrating that workers, animals, and the environment may be exposed to the vapors of chemicals added to granular diets are presented. When 1,3,5-trichlorobenzene (TCB), a moderately volatile solid, was added to the granular diet of rats at 5 g TCB/kg diet, vapor-phase TCB was detected in room air (30 ppb), cage air (1-130 ppm), and air samples obtained in the clean and return corridors outside the room. About 4 g/day were exhausted to the atmosphere. (12 refs)

- 79-0822 Metabolic Activation of 2,4-Diaminoanisole, a Hair-Dye Component--II. Role of Cytochrome**

P-450 Metabolism in Irreversible Binding In Vitro. (Eng) Dybing, E. (Dept. Environment Toxicology, Natl. Inst. Public Health, Oslo 1, Norway); Aune, T.; Nelson, S. D. *Biochem Pharmacol* 28(1): 43-50; 1979.

The possibility that cytochrome P-450 metabolism leads to the formation of reactive forms of 2,4-diaminoanisole (2,4-DAA) that bind irreversibly, to protein and other macromolecules was investigated. Incubation of rat liver microsomes with 3 H-2,4-DAA in the presence of NADPH and O_2 led to the formation of products irreversibly bound to microsomal protein. The binding was inhibited by a $CO:O_2$ atmosphere and by an antibody against NADPH cytochrome c reductase. Addition of cytochrome P-450 inhibitors such as SKF 525-A and metyrapone also inhibited binding, whereas α -naphthoflavone slightly stimulated binding rates, β -naphthoflavone had no effect. Pretreatment of animals with phenobarbital increased binding rates to 175% of controls. Experiments with 3 H- and 14 C-ring-labeled 2,4-DAA indicated some loss of 3 H, which was confirmed by isolation of labile 3 H. Substitution of the H's in the methyl group with deuterium led to increases in both binding and mutagenicity of 2,4-DAA. Formation of formaldehyde and a small amount of methanol could be demonstrated during the oxidative metabolism of methyl-labeled 2,4-DAA. Addition of superoxide dismutase and ascorbic acid inhibited binding, and a small amount of irreversible binding could be demonstrated when NADPH was replaced by a xanthine-xanthine oxidase system. Microsomes from rat kidney also activated 2,4-DAA in the presence of NADPH. Irreversible binding could be shown with liver microsomal RNA in vitro but not with exogenous DNA. A tentative scheme involving aromatic hydroxylation, oxidative demethylation, and N-hydroxylation for the microsomal metabolism of 2,4-DAA is proposed. (26 refs)

- 79-0823 Metabolic Activation of 2,4-Diaminoanisole, a Hair-Dye Component--III. Role of Cytochrome P-450 Metabolism in Irreversible Binding In Vivo.** (Eng) Dybing, E. (Dept. Environmental Toxicology, Natl. Inst. Public Health, Oslo 1, Norway); Aune, T.; Nelson, S. D. *Biochem Pharmacol* 28(1): 51-55; 1979.

The metabolism of 2,4-diaminoanisole (2,4-DAA) and the irreversible binding of this compound in vivo were studied in male Wistar rats inoculated with 3 H-2,4-DAA (10-200 mg/kg ip). There was a linear dose response of binding to liver and kidney at 4 hr after injection. No binding to liver RNA or DNA was detected. Pretreatment of animals with the cytochrome P-450 phenobarbital and β -naphthoflavone increased binding to protein in liver and kidney, but cobaltous chloride lowered binding in both organs. Irreversible binding was preferentially localized in the endoplasmic reticulum of the liver cell; considerable binding was also found in the proteins of the cytosol. Diethyl maleate pretreatment led to a 40% increase in liver binding but had no effect on kidney binding. Unbound 3 H-2,4-DAA was rapidly cleared from plasma, liver, and kidneys (peak values were

seen at 0.5 hr). Considerable amounts of irreversibly bound material could still be demonstrated in the liver and kidneys 24 hr after a 100-mg/kg dose. Some irreversibly bound radioactivity was also found in the proteins of lungs, adrenals, and blood. The effects of inducers and inhibitors of cytochrome P-450 on 2,4-DAA binding in vivo suggest that it is dependent on cytochrome P-450 metabolism, as has been shown in vitro. The relevance of the finding of irreversible binding of 2,4-DAA to hepatic protein in vivo is uncertain. (16 refs)

- 79-0824 Analysis of Biliary and Urinary Metabolites of 3'-Methyl-4-(dimethylamino)azobenzene in Rats.** (Eng) Mori, Y. (Gifu Coll. Pharmacy, Mitahora-higashi 5-6-1, Gifu 502, Japan); Hori, T.; Toyoshi, K. *Gann* 69(6): 757-762; 1978.

Metabolites of 3'-methyl-4-(dimethylamino)azobenzene (3'-Me-DAB) in rat bile and urine were analyzed quantitatively by a radiotracer technique. ³H-3'-Me-DAB (45 mg/kg in cottonseed oil) was administered to male Wistar rats by stomach tube. Biliary and urinary metabolites collected within 24 hr after treatment were hydrolyzed with β -glucuronidase/aryl-sulfatase. The hydrolyzed metabolites were then extracted with chloroform or separated by chromatography on Amberlite XAD-2 using methanol as a solvent. The metabolites in the chloroform or methanol eluates were identified by reverse isotope dilution, before or after they were separated by thin-layer chromatography. N-Demethylated, aryl hydroxylated, and azo-reduced metabolites were detected in the bile, in addition to products oxidized at the ring methyl group (new metabolites). On the other hand, metabolites retaining the azo-linkage were the scarcely detected in urine, in which 3-aminobenzoic acid and 3-amino-6-hydroxytoluene and their N-acetylated products were the major metabolites. These results indicate that the metabolism of 3'-Me-DAB in the rat involves oxidation of the ring methyl group. The significance of the ring methyl group to the carcinogenicity of aminoazo dyes is discussed. (9 refs)

- 79-0825 Alpha-Fetoprotein During Chemically Induced Hepatocellular Carcinoma in Rats.** (Eng) Abraham-Inpijn, L. (Dept. Internal Medicine, Univ. Hosp. Wilhelmina Gasthuis, Amsterdam, Netherlands). *Trop Geogr Med* 30(2): 227-234; 1978.

When male Wistar rats were fed the hepatocarcinogens 3-methyl-4'-(dimethylamino)azobenzene or aflatoxin B₁, α -fetoprotein (AFP)-positive sera were found in the tumor-induction phase (around 50 days). At this time, the liver showed acute liver cell necrosis but no malignant changes, and the AFP level correlated with the degree of necrosis. The presence of AFP during induction was followed by a high frequency of liver tumors in later phases. The AFP concen-

tration in the tumor phase was not related to tumor histology, but was related to the degree of cirrhosis. (33 refs)

- 79-0826 Metabolism and Mutagenicity of Styrene.** (Eng) Watabe, T. (Lab. Drug Metabolism and Toxicology, Dept. Hygienic Chemistry, Tokyo Coll. Pharmacy, Hachioji-shi, Tokyo, Japan); Isobe, M.; Sawahata, T.; Yoshikawa, K.; Yamada, S.; Takabatake, E. *Scand J Work Environ Health* 4(Suppl. 2): 142-155; 1978.

The mutagenicity of styrene (SR) toward *Salmonella typhimurium* was determined in the presence and absence of a liver supernatant fraction obtained from Wistar rats pretreated with 3-methylcholanthrene (3-MC), phenobarbital (PB), or polychlorinated biphenyls (PCB) and fortified with an NADPH-generating system (S-9 mix). In some assays, the S-9 mix was preincubated in the presence of 1 mM 3,3,3-trichloropropene oxide (TCPO), a microsomal epoxide hydrolase inhibitor. SR was mutagenic toward *S. typhimurium* strain TA100 after activation with S-9 mix containing fractions from 3-MC- or PB-treated rats + TCPO. No mutagenicity was observed when TCPO was omitted or when fractions from PCB-treated rats were used. The S-9 fraction from 3-MC-treated rats was more effective than that from PB-treated animals. The mutagenicity of phenylloxirane (PO), a primary metabolite of SR, was decreased markedly by the S-9 mix, and this decrease was partially inhibited by TCPO. Gas chromatographic (GC) data indicated that PO could not account for the mutagenicity induced by the hepatic activation of SR, since the sums of PO and its hydrolysis product 1-phenyl-1,2-ethanediol (PE: formed from SR during incubation with S-9 \pm TCPO) were much smaller than the amount that induced mutagenesis. GC data also showed that PCB were the most potent inducers of hepatic monooxygenase, which catalyzes the conversion of SR to PO. PCB were 1.4 times as effective as 3-MC in spite of their inability to increase the hepatic activation system for SR mutagenicity. Therefore, at least one more unknown active metabolite with an epoxide structure may be present. Evidence is presented for the NADPH-dependent covalent binding of SR to rat liver microsomal protein. This binding was increased by TCPO in vitro and by PB pretreatment of rats in vivo and decreased by pretreatment of rats with carbon tetrachloride. (38 refs)

- 79-0827 Effects of Long-term Oral Administration of Styrene to Mice and Rats.** (Eng) Ponomarev, V. (International Agency Res. Cancer, Lyon, France); Tomatis, L. *Scand J Work Environ Health* 4(Suppl. 2): 127-135; 1978.

In long-term carcinogenicity tests, styrene (SR) monomer was given po to female O₂₀ mice (1,350 mg/kg) C57Bl mice (300 mg/kg), and BD IV rats (1,350 mg/kg) on gestation day 17, and their offspring were treated weekly with SR by stom-

ach tube from the time of weaning throughout their life-span. Weekly doses were 1,350 mg/kg for O₂₀ mice, 300 mg/kg for C57Bl mice, and 500 mg/kg for BD IV rats. Following continuous SR administration for > 100 wk, there was a significantly increased and earlier incidence of lung tumors in male and female O₂₀ mice compared with olive oil-treated controls. Histologically, the lung tumors were adenomas or adenocarcinomas, and the proportion of benign and malignant lung tumors was similar in the various groups. SR was severely toxic to O₂₀ mice, particularly in the liver, and it shortened the life-span considerably. Tumor incidence in C57Bl SR-treated mice was not significantly different from that seen in controls; there was a slightly increased incidence of liver tumors in males. Although total tumor incidence was also not significantly different from that of controls, BD IV rats developed a few tumors not ordinarily seen in control animals. These consisted of three stomach tumors and three neurogenic tumors. The results provide weak evidence of the carcinogenicity of SR in O₂₀ mice when given at a high dose level. (7 refs)

- 79-0828 Phenacetin Studies (Letter to Editor).** (Eng) Cuatrecasas, P. (Wellcome Res. Lab., Burroughs Wellcome Co., Research Triangle Park, NC, 27709). *Ann Intern Med* 203(4375): 6-7; 1979.

Several long-term studies of the carcinogenicity of phenacetin in laboratory animals are cited to demonstrate that there is no positive evidence of tumor induction by this compound. Hence, the recent inclusion of phenacetin in a list of "chemicals known to be carcinogenic in man" introduces an error and gives wide circulation to misinformation. (3 refs)

- 79-0829 Effects of Dietary Butylated Hydroxytoluene and Phenobarbital on the Activities of Ornithine Decarboxylase and Thymidine Kinase in Rat Liver and Lung.** (Eng) Saccone, G. T. (Dept. Food Microbiology and Toxicology, Food Res. Inst., Univ. Wisconsin-Madison, Madison, WI, 53706); Pariza, M. W. *Cancer Lett* 5(3): 145-152; 1978.

The hypothesis that butylated hydroxytoluene (BHT) and phenobarbital (PB) stimulate increases in ornithine decarboxylase (ODC) activity as an essential part of their mode of action in inducing hyperplasia in rat liver was investigated. Male Sprague-Dawley rats were entrained to an inverted 12-hr dark/12-hr light cycle, with food (60% casein diet \pm 0.5% BHT or 0.05% PB) being available during the first 2 hr of the dark period. A characteristic diurnal oscillation in hepatic ODC activity was noted in control animals under these conditions. BHT and PB had no appreciable effect on this activity during the first 3 days of feeding. Hepatic thymidine kinase (TK) activity, however, was stimulated 4-10 times at 3 days. In lungs from the same animals, ODC and TK activities were unchanged. On the third day of BHT feeding,

the incorporation of ³H-thymidine into liver DNA was stimulated in a manner that correlated well with the observed increase in TK activity during most of this day. In lung DNA, ³H-thymidine incorporation was decreased (approx 50% of controls) after BHT feeding. The effects of BHT were transitory, as on day 22 no differences were found between BHT-fed and control rats with respect to the biochemical parameters studied. It is concluded that if there is a critical and rate-limiting hepatic growth "step" actuated by BHT and PB, it cannot be ODC. (15 refs)

- 79-0830 Hydantoin-induced Lymphadenopathies and Lymphomas.** (Eng) Rausing, A. (Univ. Inst. Pathology General Hosp., S-21401 Malmo, Sweden). *In: Recent Results Cancer Res* 64: 263-264; 1978.

In light of the accumulating evidence that hydantoin derivatives used as anticonvulsants (AC's) are related to the development of lymphadenopathies and malignant lymphomas, the records of the Swedish Adverse Drug Reaction Committee were investigated. Between 1967 and 1977, nine cases of lymph node (LN) complications in AC users were identified, three of which were on diphenylhydantoin (DPH), three on mephenetoin (MPT), and three on carbamazepine (CAP). During this time, the number of epileptics in Sweden was approx 40,000. Apparently, LN enlargement in patients taking AC's is rare. CAP has not previously been reported as a cause of LN enlargement, but in view of its immunosuppressive effect similar to that of the hydantoins, such a reaction may well exist. In another study, the clinical records of patients with malignant lymphoma and Hodgkin's disease were examined for AC use at the Institute of Pathology, Malmo, Sweden. Among the 451 records examined, 3 patients with immunoblastic histiocytic lymphoma had taken these drugs (DPH, MPT, and CAP, respectively) and 1 patient with well-differentiated lymphocytic lymphoma had taken DPH. Although this frequency is not high, there is a suggestion of a true increased risk, especially in the immunoblastic group. (5 refs)

- 79-0831 Hydantoin-induced Lymphadenopathies and Lymphomas: Experimental Studies in Mice.** (Eng) Krueger, G. R. (Labor fur Immunopathologie, Pathologisches Institut der Universitat Koln, Lindenburg, D-5000 Koln 41, W. Germany); Bedoya, V. A. *In: Recent Results Cancer Res* 64: 265-270; 1978.

Diphenylhydantoin (DPH) was administered (6 mg/100 g in liquid diet) to female mice of three strains: C3Hf, resistant to lymphoma development; C57BL, which show a low spontaneous incidence of lymphomas and leukemias; and SJL/J, which exhibit a high spontaneous incidence of malignant lymphomas. Groups of mice were autopsied every 8 wk beginning 6 wk after initiation of treatment, and tissues were studied with histological techniques, immunofluorescence,

and electron microscopy. No C3Hf mice developed tumors, whereas 12% of C57BL (vs 4% of controls) and 25% of SJL/J mice (vs 0% of controls) developed thymic lymphoblastic lymphomas. The tumor cells were occasionally slightly positive for acid phosphatase; no B- or T-cell markers were demonstrated. Tumors were successfully transplanted sc into isogenic mice in 80% of the cases. Electron microscopy showed the tumor cells to be predominantly lymphoblastic in nature, with widened perinuclear cisternae, dilated endoplasmic reticulum, and mitochondria showing loss of cristae and occasional incorporation of ribosomelike material as well as myelinic structures. No virus-related cytopathic changes or intracellular C-type viral particles were noted. It appears that DPH is effective in producing atrophic and reactive changes in immunocompetent tissues with coincident reticulohistiocytic hyperplasia. (14 refs)

79-0832 Monoclonal Gammopathy and Subsequent Multiple Myeloma in a Patient on Chronic Diphenylhydantoin Therapy. (Eng) Matzner, Y. (Dept. Hematology, Hadassah Univ. Hosp. and Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Polliack, A. *Isr J Med Sci* 14(12): 1265-1267; 1978.

The case of a patient who developed monoclonal gammopathy followed by classical multiple myeloma while receiving chronic diphenylhydantoin (DPH) therapy is presented. The patient, a 54-yr-old man, had been receiving DPH for 20 yr for the treatment of epilepsy. At the time of the first hospitalization, hypertension, hypertensive retinopathy, left hemiparesis, and mild axillary lymphadenopathy were present. RBC sedimentation rate was raised to 100 mm (West), and there was proteinuria of 2-10 g/day. Serum protein electrophoresis revealed the presence of a paraprotein between the β and γ regions, which constituted 29% of the total protein. Eight months later, while the patient was still receiving DPH, he was hospitalized because of cellulitis, septic shock, bone pain, and wt loss. Serum and urine immunoelectrophoresis revealed the presence of an IgG- γ paraprotein. The diagnosis of multiple myeloma was made at this time. Continuous melphalan therapy (2 mg/day) was started, and diphenylhydantoin therapy was discontinued. The patient remains in remission after 2 yr of follow-up. The authors suggest that periodic clinical examination and repeated serum electrophoresis be performed in patients receiving diphenylhydantoin therapy. (24 refs)

79-0833 Metabolic Conversion of 1- and 2-Nitronaphthalene to 1- and 2-Naphthylamine in the Rat. (Eng) Johnson, D. E. (Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ, 08876); Cornish, H. H. *Toxicol Appl Pharmacol* 46(3): 549-553; 1978.

The possible conversion of 1- and 2-nitronaphthalene (1- and 2-NN) to the corresponding naphthylamines was studied fol-

lowing ip injection of 100 mg/kg 1- or 2-NN into the adult male Sprague-Dawley rats. The gas-liquid chromatographic retention times and mass fragmentation spectra of the 2-naphthylamine isolated as a metabolite of 2-NN and the 1-naphthylamine isolated as a metabolite of 1-NN were identical to those of the 2- and 1-naphthylamine standards, respectively. Evidence that the metabolism of NN's leads to the formation of the corresponding amines, one of which (β -naphthylamine) is a known carcinogen, suggests that human exposure to these compounds should be minimal. It also points out the important role of metabolic studies in the evaluation of potential chemical toxicity and suggests a critical reevaluation of compounds whose metabolism by known pathways could lead to the in vivo formation of carcinogenic compounds. (16 refs)

79-0834 In Vitro Reductive Metabolism of N-Nitrosodibenzylamine: Evidence for New Reactive Intermediates. (Eng) Gal, J. (Dept. Pharmacology, Div. Clinical Pharmacology: C237, Sch. Medicine, Univ. Colorado Medical Center, Denver, CO, 80262); Estin, C. D.; Moon, B. J. *Biochem Biophys Res Commun* 85(4): 1466-1471; 1978.

N-Nitrosodibenzylamine (DBNA: 1.0 or 0.10 mM) was incubated anaerobically with whole-liver homogenates from seven rabbits (6 male, 1 female) for 30 min, and organic extracts of the incubation products were analyzed by gas chromatography and mass spectrometry. One of the incubation products was identified as bibenzyl. Incubation of DBNA with whole blood under the conditions used for liver preparations gave no detectable bibenzyl. No bibenzyl was obtained when 1,1-dibenzylhydrazine or dibenzylamine was used as substrate. The formation of bibenzyl from DBNA is the result of a 2-electron reduction of the substrate to 1-hydroxy-2,2-dibenzylhydrazine, an unstable compound that breaks down to bibenzyl and nitrogen. The metabolic 2-electron reduction of nitrosamines results in highly reactive intermediates such as N-hydroxyhydrazines and diazenes, some of which are known to react with nucleophiles. (15 refs)

79-0835 Carcinogenicity Studies on Different Diarylide Yellow Pigments in Mice and Rats. (Eng) Leuschner, F. (Laboratorium für Pharmakologie und Toxikologie, Hamburg, W. Germany). *Toxicol Lett* 2(5): 253-260; 1978.

The carcinogenicity of three pure diarylide yellow pigments and one contaminated with 3,3'-dichlorobenzidine (DCB) was tested in mice (NMRI, Ivanovas) and rats (Sprague-Dawley, Ivanovas). The pigments were administered in the feed at concentrations of 0.1%, 0.3%, and 0.9% (av 215, 650, and 1,960 mg/kg/day in mice and 68, 205, and 630 mg/kg/day in rats) for 104 wk. A fifth diarylide pigment was given to five rabbits in a single po dose of 50 mg/kg. Metabolism to DCB or 3,3'-dimethylbenzidine (DMB) was determined by

urinalysis after 6 and 23 mo in the mice and rats and after 48 and 72 hr in the rabbits. Mice and rats tolerated the pigments up to the 0.9% dietary level; there were no adverse effects on growth, food intake, health condition, survival, or the histological appearance of major tissues and organs, even when DCB (20 ppm) was added to the one pigment. Neither DCB nor DMB was detected in urine samples of mice, rats, or rabbits; the analytical methods were sensitive to concentrations as low as 3 µg/10 ml urine. It is unlikely, therefore, that these pigments will present a health hazard or an increased carcinogenic risk to the population exposed via manufacturing and usage as long as the contamination level of DCB and DMB is kept under control. (21 refs)

79-0836 Uptake of Glucuronides into Isolated Hepatocytes and Their Effects on Glucuronide and Sulfate Conjugation. (Eng) Norling, A. (Dept. Forensic Medicine, Karolinska Institutet, S-104 01 Stockholm, Sweden); Andersson, B.; Berggren, M.; Moldeus, P. *Acta Pharmacol Toxicol (Kbh)* 43(4): 311-317; 1978.

Uptake studies, using radioactive 4-nitrophenyl glucuronide and phenolphthalein glucuronide, have demonstrated the ability of these glucuronides (GCN) to enter isolated rat hepatocytes. However, the intracellular distribution and cellular binding of the two GCN's differed. These differences may be due to their varied mol wts of lipophilicity. The differences in cellular binding of the GCN's are also reflected in their ability to interfere with uridine diphosphate-glucuronosyltransferase activity. (16 refs)

79-0837 Possible Carcinogenetic Properties of a New Chromogen, Dicarboxydine (γ,γ' -3,3'-Benzidine Dioxidybutyric Acid), Tested in Rats and Mice. (Eng) Pliss, G. B. (Lab. Carcinogenic Agents, Petrov Res. Inst. Oncology, 68 Leningradskaya St., Pesochny-2, Leningrad 188646, USSR); Volfson, N. I. *J Natl Cancer Inst* 62(2): 301-304; 1979.

The carcinogenic potential of γ,γ' -3,3'-benzidinedioxidybutyric acid (dicarboxydine:DCD) was tested in 208 white noninbred rats and 127 CC57BR mice. Rats were injected sc with 35 or 45 mg DCD in sunflower oil 1x/wk or fed 20 mg in the diet 5x/wk, all for 24 mo. Mice received 4 mg DCD or 3 mg dianisidine dihydrochloride (DAZ) sc 1x/wk or 3 mg DCD in the diet 5x/wk, all for 18.5 mo. Although 21/99 surviving rats developed tumors, there was no significant difference in tumor incidence between treated and control groups. The av latent period in the treated rats was always > 18 mo. Only single cases of tumors occurred at sites other than those in the four control animals, and they were in the bladder, prostate gland, uterine body, and other organs. Four rats developed sarcomas, but only at the injection site. Of 72 surviving mice, 18 developed tumors, 9 of which were liver hemangiomas and 2 lung adenomas. Three control mice de-

veloped tumors. Correlation of the results obtained in the experimental and control groups of mice and the oncogenic characteristics of CC57BR mice, led to the conclusion that DCD and DAZ have no carcinogenic effects in these animals. The longer period of tumor induction in treated animals, the paucity of tumors after po administration in rats, and the lack of carcinogenic effect in mice indicate that DCD is of dubious or negative carcinogenicity. (9 refs)

79-0838 Detection of the 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) Receptor in Rat Liver by Isoelectric Focusing in Polyacrylamide Gels. (Eng) Carlstedt-Duke, J. (Dept. Chemistry, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Elfstrom, G.; Snochowski, M.; Hogberg, B.; Gustafsson, J. A. *Toxicol Lett* 2(6): 365-373; 1978.

Isoelectric focusing in polyacrylamide gels was used to detect the 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) receptor in rat liver. Both serum and liver cytosol from young male Sprague-Dawley rats contained a dextran-coated charcoal-resistant (^3H)-TCDD-binding protein, the serum-binding protein having a larger capacity than the cytosol-binding protein. The serum-binding protein focused as a sharp peak with pI 5.7 to 5.8, whereas the cytosol-binding protein focused as several peaks with variable pI's. The cytosol TCDD receptor could be completely separated from the serum binder by trypsin treatment and isoelectric focusing. The binding of (^3H)-TCDD to the receptor was competed for by 2,3,7,8-tetrachlorodibenzofuran, 3-methylcholanthrene, and β -naphthoflavone, but not by phenobarbital, pregnenolone-16 α -carbonitrile, 17 β -estradiol, testosterone, progesterone, or dexamethasone. 79-0839 Mutagenicity of Anthraquinone and Benzanthrone Derivatives in the Salmonella/Microsome Test: Activation of Anthraquinone Glycosides by Enzymic Extracts of Rat Cecal Bacteria. (Eng) Brown, J. P. (Dynapol, 1454 Page Mill Road, Palo Alto, CA, 94304); Dietrich, P. S. *Mutat Res* 66(1): 9-24; 1979.

The mutagenicity of 70 anthraquinones (AQ's) and 20 benzanthrone derivatives was assayed using five tester strains of *Salmonella typhimurium* and Aroclor 1254-induced rat liver microsomes. Of the 68 9,10-AQ derivatives, 28 exhibited frameshift mutagenicity with microsomal activation. The incidence of mutagenicity was even higher for phenolic AQ's (13/25) and nitro-AQ's (3/3). The most potent mutagens were of plant origin, with lucidin (1,3-dihydroxy-2-hydroxymethylanthraquinone) and its 2-ethyl ether (1,3-dihydroxy-2-ethoxymethylanthraquinone) giving the highest revertants per nanomole, 70 and 82 respectively, with strain TA100. A number of glycosides of mutagenic hydroxy-AQ's were nonmutagenic in the standard assay, but they were activated by pretreatment with cell-free sonic ex-

tracts of rat cecal bacteria. This group included alizarin-2-O- β -D-glycoside, emodin-1(8)monoglucoside, and lucidin-3-O-primveroside. Eight of the 22 benzantrones tested exhibited frameshift mutagenicity for *Salmonella*. All were substituted in the C-3 position with oxygen, nitrogen, or sulfur. The most potent of the group was 3-(4-toluidino)-benzanthrone, exhibiting about 65 revertants/nanomole in strain TA98 with microsomal activation. Benzantrones substituted solely with halogens or sulfonates were nonmutagenic. (17 refs)

79-0840 A Relationship Between Repression of Dimethylnitrosamine-demethylase by Polycyclic Aromatic Hydrocarbons and Their Shape. (Eng) Kaliszan, R. (Dept. Physical Chemistry, Medical Acad., K. Marksa 107, 80-416 Gdansk, Poland); Lamparczyk, H.; Radecki, A. *Biochem Pharmacol* 28(1): 123-125; 1979.

The quantitative relationship between the ability of polycyclic aromatic hydrocarbons (PAH) to repress the mixed-function oxidase, dimethylnitrosamine demethylase, and a parameter expressing the shape of the PAH molecules was examined. The shape parameter represents the ratio of the longer to shorter sides of the minimum rectangular envelope around the structure, drawn proportionally to atomic dimensions. Use of the shape parameter allowed satisfactory prediction of the biological activity of 23 active and 4 inactive compounds; the results were unsatisfactory for 8 compounds. However, the correlation between the shape parameter and repressor activity toward dimethylnitrosamine-demethylase generally supports a previous suggestion regarding the importance of steric fit between the PAH molecule and its cellular receptor site. (8 refs)

79-0841 Carcinogenicity of Polycyclic Aromatic Hydrocarbons Studied by SIMCA Pattern Recognition. (Eng) Norden, B. (Dept. Organic Chemistry, Inst. Chemistry, Univ. Umea, S-90187 Umea, Sweden); Edlund, U.; Wold, S. *Acta Chem Scand B* 32(8): 602-608; 1978.

The carcinogenicity of 32 polycyclic aromatic hydrocarbons was determined on the basis of a multivariate statistical analysis of 15 theoretical, unmeasured variables and 8 measured variables. A prediction of the level of carcinogenicity for the active compounds was also made. (26 refs)

79-0842 The Effect of Sample Environment on the Room-temperature Phosphorescence of Several Polynuclear Aromatic Hydrocarbons. (Eng) Bower, E. L. (Materials Science & Engineering, Univ. Florida, Gainesville, FL, 32611); Winefordner, J. D. *Anal Chim Acta* 102(1): 1-13; 1978.

The heavy-atom effect produced significant enhancement of room-temperature phosphorescence (RTP) signals for several polycyclic aromatic hydrocarbons (PAH), the hierarchy being $Tl+ > Ag+ > Pb^{2+} > Hg^{2+}$. $Tl+$ also enhanced the spectral features of emission bands. RTP was induced from PAH on both sodium acetate and filter paper sample supports. Anomalous results were obtained in a study of the effect of various gaseous environments. (40 refs)

79-0843 High Pressure Liquid Chromatographic Determination of Polynuclear Aromatic Hydrocarbons in Oysters. (Eng) Hanus, J. P. (Food and Drug Admin., 3032 Bryan St., Dallas, TX, 75204); Guerrero, H.; Biehl, E. R.; Kenner, C. T. *J Assoc Off Anal Chem* 62(1): 29-35; 1979.

Reverse-phase high-pressure liquid chromatography was used to determine 13 polynuclear aromatic hydrocarbons in oysters at the 2-ppb level. Recoveries from spiked samples generally were $> 80\%$. (15 refs)

79-0844 Clastogenic Effects of Frusemide on Human Leukocytes in Culture. (Eng) Jameela (Cytogenetics Lab., Dept. Genetics, Osmania Univ., Hyderabad 500007, India); Subramanyam, S.; Sadasivan, G. *Mutat Res* 66(1): 69-74; 1979.

The clastogenic effects of the diuretic frusemide were evaluated in human chromosomes in vitro. Cultures of WBC from normal donors were exposed to three concentrations of frusemide (0.2, 0.4, or 0.8 mg/ml) for 24 or 72 hr, and 100-110 metaphases were scored. There was a decrease in the mitotic index after both treatment times. The induction of chromosome aberrations was dose-dependent. There was a significant increase of moderate damage (gaps and breaks) and a low incidence of multiple aberrations after 24 hr exposure, but the reverse was true after 72 hr exposure. Exchanges, dicentric, and acentric were only seen after 24 hr exposure. The total percentage of aberrations was higher after 24 hr exposure. The predominance of chromatid over chromosome aberrations suggests that the drug acts during the S and G₂ phases of the cell cycle. Exchanges were significant at all doses except 0.2 mg/ml in the 24-hr test, which indicates the chromosome-breaking potential of the chemical. The absence of exchanges after 72 hr exposure may be due to their high instability. It is concluded that frusemide is capable of causing chromosome mutations. (19 refs)

79-0845 Potential Proximate Carcinogens of 7,12-Dimethylbenz(a)anthracene: Characterization of Two Metabolically Formed *trans*-3,4-Dihydrodiols (Letter to Editor). (Eng) Yang, S. K. (Dept. Pharmacology, Sch. Medicine, Uniformed Services Univ. Health Sciences, Bethesda, MD, 20014); Chou, M. W.; Roller, P. P. *J Am Chem Soc* 101(1): 237-239; 1979.

Two previous unreported metabolites of 7,12-dimethylbenz(a)anthracene (DMBA) were obtained by in vitro incubation of DMBA with rat liver microsomes and a NADPH-generating system at 37 C for 1 hr. The structure of the two resulting optically active trans-3,4-dihydrodiols was characterized in detail. Upon further metabolism, they had greater in vitro DNA-binding and mutagenic activity than their parent hydrocarbons [DMBA and 7-hydroxymethyl-12-methylbenz(a)anthracene] and therefore are potential proximate carcinogens. Multiple activation pathways may contribute to the biological activities of DMBA. (21 refs)

79-0848 Spectroscopic Studies of In Vivo and In Vitro Nucleic Acid-Carcinogen Interactions (Meeting Abstract). (Eng) Ivanovic, V. (New York Univ., New York, NY, 10003). *Diss Abstr Int B* 39(6): 2823; 1978. (no refs)

79-0849 Mutagenicity of Polycyclic Hydrocarbons. V. Induction of Sister-Chromatid Exchanges In Vivo. (Eng) Roszinsky-Kocher, G. (Dept. Human Genetics and Anthropology, Universitätsstrasse 1, Geb. 23.12, D-4000 Dusseldorf 1, W. Germany); Basler, A.; Rohrborn, G. *Mutat Res* 66(1): 65-67; 1979.

The ability of polycyclic hydrocarbons to induce sister chromatid exchanges (SCE's) at concentrations too low to induce chromosomal aberrations was tested in 8- to 12-wk-old Chinese hamsters. The animals received two injections of test compound (450 mg/kg x 2, ip) 24 hr apart. Bone marrow chromosomes were prepared 24 hr after the second injection. The most potent SCE-inducing compound was benzo(a)pyrene (BP: 10.6 SCE's/metaphase). The av number of SCE's per cell induced by benzo(a)anthracene, benzo(b)fluoranthene, benzo(e)pyrene, phenanthrene, chrysene, and dibenzanthracene was 4.9-6.1. The number of anthracene-induced SCE's per metaphase (3.7) was not increased compared with that in controls (3.9). Only BP significantly increased the number of metaphases with chromosomal aberrations. These

results correlate with those from the *Salmonella typhimurium*/microsome mutagenicity assay and with the carcinogenicity of the test compounds. (6 refs)

79-0850 Mutagenicity and Tumor-initiating Activity of Fluorinated Derivatives of 7,12-Dimethylbenz(a)anthracene. (Eng) Huberman, E. (Biology Div., Oak Ridge National Lab., Oak Ridge, TN, 37830); Slaga, T. J. *Cancer Res* 39(2, Part 1): 411-414; 1979.

7,12-Dimethylbenz(a)anthracene (DMBA) and its 1-, 2-, 5-, and 11-fluoro derivatives were tested for mutagenicity in Chinese hamster V79 cells and skin tumor initiation in Sencar (skin-tumor-sensitive) mice. Direct mutagenicity was investigated by treating the cells for 2 days with 0.01-38 μ M of DMBA or one of its derivatives and measuring the number of ouabain-resistant mutants. None of the compounds were mutagenic in this assay, nor were they cytotoxic, as measured by the cloning efficiency of the treated cells. However, when cell-mediated mutagenicity was measured by treating V79 cells cocultivated with normal golden hamster embryonic fibroblasts, which unlike the V79 cells, can metabolize polycyclic aromatic compounds, DMBA, 1-fluoro-DMBA, 5-fluoro-DMBA, and 11-fluoro-DMBA exhibited dose-dependent mutagenicity and reduction of cloning efficiency of the V79 cells. 11-Fluoro-DMBA was as active as DMBA in these respects, whereas the 1- and 5-fluoro derivatives were 3 orders of magnitude less active than DMBA. The tumor-initiating activity of DMBA and its derivatives was tested to determine whether their metabolism to mutagenic derivatives is correlated with carcinogenicity. Single topical applications of 100 nanomoles of initiator to the mice were followed 1 wk later by applications of 12-O-tetradecanoylphorbol-13-acetate (5 μ g 2x/wk) as promoter. After 15 wk of promotion, both DMBA and 11-fluoro-DMBA had induced papillomas in 100% of the surviving mice (39/40 and 38/40 treated respectively), and there were >20 papillomas/mouse. In contrast, 1-fluoro-DMBA and 5-fluoro-DMBA were weak initiators, with only 10% and 20% tumor-bearing animals, respectively, and 2-fluoro-DMBA was inactive (only 3% tumor bearers). The results indicate that fluorination of DMBA at positions 1, 2, or 5 eliminates >99% of the mutagenic activity of DMBA for V79 cells and reduces its tumor-initiating activity by \geq 85%. (40 refs)

79-0851 The Effects of Hyaluronidase upon Tumor Formation in BALB/c Mice Painted with 7,12-Dimethylbenz(a)anthracene. (Eng) Pawlowski, A. (Clinical Science Div., Dermatology Section, Medical Sciences Bldg., Univ. Toronto, Toronto, Ontario M5S 1A8, Canada); Haberman, H. F.; Menon, I. A. *Int J Cancer* 23(1): 105-109; 1979.

The effects of hyaluronidase on 7,12-dimethylbenz(a)anthracene (DMBA) carcinogenesis were studied in BALB/c mice. Group 1 mice were painted with a 1% soln of DMBA, Group 2 mice were painted with DMBA and injected id with 0.2 ml of 0.1% hyaluronidase, and Group 3 mice were injected with physiological saline or heat-inactivated hyaluronidase and painted with DMBA. Treatments were given twice weekly for 5 wk. Compared with the mice in Groups 1 and 3, Group 2 mice showed fewer cutaneous tumors, fewer tumors per mouse, smaller tumors, a shorter latency period to appearance of tumor, and a smaller frequency distribution of the mitotic index of the skin outside the tumors. The internal organs were free of lesions except for a metastatic lesion in the lymph node of one Group 3 mouse. The data indicate that hyaluronidase decreases the carcinogenicity of topically applied DMBA. (17 refs)

79-0852 Carcinogenesis after Two Administrations of DMBA to Rats in Different Life Periods. (Rus)

P' rvanova, L. G. (Lab. Experimental Tumors, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR). *Vopr Onkol* 24(11): 96-99; 1978.

To evaluate the cumulative carcinogenic effect of transplacental and postnatal administration of 7,12-dimethylbenz(a)anthracene (DMBA), the random-bred albino female rats were divided into four groups: animals in Group 1 had transplacental exposure to DMBA (iv injection at 15 mg/kg to mothers on day 19-20 of the pregnancy), rats in Group 2 received DMBA postnatally on day 90-92, animals in Group 3 had transplacental and postnatal exposure, and rats in Group 4 served as nontreated controls. All animals were followed for 18 mo. In Group 1, 25/54 rats developed 28 tumors: 10/25 rats had tumors of the peripheral and central nervous system, 8 had tumors of the kidney, and 5 had tumors of the mammary gland (there were also leiomyomas of the small intestine, hypophyseal adenomas, glandular polyps of the uterus, hemangiopericytomas of the uterus, and hemangiosarcomas). In Group 2, 22/58 rats had 25 tumors (80% of the tumors were located in the mammary gland). In Group 3, 36/55 rats developed 56 tumors (including 19 tumors of the mammary gland, 10 neurogenic tumors, 6 kidney tumors, 2 thecafolliculomas of the ovaries, 1 adenoma of the thyroid, 2 adenomas of the hypophysis, 1 polyp of the stomach, 1 angiosarcoma of the hind extremity, and 1 lympholeukemia). Only 3/64 of the rats in Group 4 had tumors (thymoma, adenoma of the thyroid, and stromal sarcoma of the endometrium). The av life span of rats in Group 3 was 321 days, compared with 369 days in Group 1, 429 days in Group 2, and 543 days in Group 4. (12 refs)

79-0853 Effect of Deoxycholic Acid on 7,12-Dimethylbenz(a)anthracene-induced, Two-Stage Mouse Skin Carcinogenesis. (Eng) Glauert, H. P. (Food Science and Human Nutrition Dept., Michigan State Univ., East Lansing,

MI, 48824); Bennink, M. R. *Res Commun Chem Pathol Pharmacol* 22(3): 609-612; 1978.

The effect of deoxycholic acid on 7,12-dimethylbenz(a)anthracene-croton oil-induced two-stage skin carcinogenesis was investigated in CF-1 mice. Two wk following initiation with 7,12-dimethylbenz(a)anthracene (DMBA, 75 g), one of the following treatments was started: (a) 0.5% croton oil, 2x/wk; (b) 0.5% croton oil, 2x/wk, plus 1% deoxycholic acid, 3x/wk; (c) 1% deoxycholic acid, 5x/wk; or (d) acetone or ethanol vehicle, 5x/wk, as controls. The only animals to develop tumors were those that received either both DMBA initiation and croton oil promotion, or DMBA initiation and croton oil and deoxycholic acid during promotion. Mice receiving deoxycholic acid in addition to croton oil during promotion tended to develop significantly more tumors per animal than did mice receiving croton oil alone as a promoter (3.25 versus 18.11 tumors/animal at 12 wk; 10.4 versus 22.1 tumors/animal at 20 wk). In addition, the latency period for the development of tumors was shorter in those receiving deoxycholic acid plus croton oil (9.6 ± 2.3 wk) than in those receiving croton oil alone (12.0 ± 2.4 wk). Deoxycholic acid could be acting either as a tumor initiator or as a tumor promoter. The increased tumor incidence could also be caused by an increase in the toxicity or absorption of croton oil due to deoxycholic acid. (11 refs)

79-0854 Effects of Stress on DMBA-induced Tumor Growth, Plasma Corticosterone and Brain Biogenic Amines in Rats. (Eng) Bhattacharyya, A. K. (Dept. Pharmacology, Howard Univ. Coll. Medicine, Washington, DC, 20059); Pradhan, S. N. *Res Commun Chem Pathol Pharmacol* 23(1): 107-116; 1979.

The development of 7,12-dimethylbenz(a)anthracene (DMBA)-induced tumors in female Sprague-Dawley littermate rats subjected to 6 wk of (1) immobilization or (2) overcrowding plus high-pitched sound was studied. DMBA was administered to the rats intragastrically (in peanut oil), at a dose of 5 mg/wk for 5 wk. Tumor growth was markedly inhibited by both types of stress, particularly immobilization. Tumors were measurable in all nonstressed control animals, but they were measurable in only 7/10 of the overcrowded-sound-stressed animals and in only 5/9 immobilized rats. Plasma corticosterone levels were significantly higher and norepinephrine levels in the diencephalon-midbrain were significantly lower in the stressed rats compared with the nonstressed controls. There were no significant changes in the brain dopamine or serotonin levels in the stressed rats. The data indicate a possible involvement of neuroendocrine mechanisms in stress-induced inhibition of tumor growth. (20 refs)

79-0855 Inhibition of 7,12-Dimethylbenz(a)anthracene-induced Mammary Tumorigenesis in Rats by a Synthetic Protease Inhibitor, N,N-Dimethylamino-

[p-(p') - guanidinobenzoyloxy]] benzilcarbonyloxyglycolate. (Eng) Yamamura, M. (Dept. Surgery, Kansai Medical Univ., 1 Fumizoncho, Moriguchi 570, Japan); Nakamura, N.; Fukui, Y.; Takamura, C.; Yamamoto, M.; Minato, Y.; Tamura, Y.; Fujii, S. *Gann* 69(6): 749-752; 1978.

Female albino Sprague-Dawley rats were inoculated iv with 2.5 mg/100 g 7,12-dimethylbenz(a)anthracene (DMBA), and then half were fed the synthetic protease inhibitor N,N-dimethylamino- [p-(p'-guanidinobenzoyloxy)]benzilcarbonyloxyglycolate (MeDBG: 0.1% of diet) for 40 days. MeDBG depressed the induction of breast tumors (7/21 rats had tumors at 120 days vs 14/22 control rats treated only with DMBA), delayed the latent period (from 29 days to 57 days), and significantly reduced the number of tumors per rat (from 2.25 to 0.48) and the av wt of tumors per rat (from 8.25 g to 0.18 g). These findings suggest that protease may play an important role in mammary tumorigenesis. (16 refs)

79-0856 A Proposed Selective Cell Carcinogenesis in Mammary Tumors. (Eng) King, T. I. (Div. Surgical Pathology, Univ. Alabama, 619 S. 19th St., Birmingham, AL, 35233); Murad, T. M.; Waksal, S. *Am J Pathol* 93(3): 655-660; 1978.

To determine if a specific carcinogenic agent has a causal effect on the proliferation of only one cell type or on all cells in the breast secretory unit, enzyme histochemistry and electron microscopy were employed to analyze dimethylbenzanthracene (DMBA)-induced mammary tumors in female Sprague-Dawley rats and virus-associated mammary tumors in C3H/HEJ mice. The results revealed that DMBA initially affects myoepithelial cell proliferation, while the virus-associated carcinoma originated from ductular epithelial cell proliferation. Tissue culture was then used to determine if a given tumor is composed of a single cell type. Electron microscopic investigation disclosed large numbers of virus particles in the cultured murine tumors. This evidence suggests that tissue culture may be used to enhance virus recovery (following fixing for examination). It is concluded that, in the mammary gland, selective cell carcinogenesis is operative in the formation of such myoepithelial and ductular epithelial tumors. (14 refs)

79-0857 Serial Transplantation of Chemical Carcinogen-induced Mouse Mammary Ductal Dysplasias. (Eng) Medina, D. (Dept. Cell Biology, Baylor Coll. Medicine, Texas Medical Center, Houston, TX, 77030). *J Natl Cancer Inst* 62(2): 397-405; 1979.

The results are presented of serial transplantation of a group of mammary dysplasias induced by administering either 7,12-dimethylbenz(a)anthracene (DMBA) (1.0 mg ig 1x/wk for 4, 6, or 9 wk) to BALB/c mice or urethan (20 mg/mouse) for 20 wk to (C57BL x DBA)F₁ mice. The incidence of mam-

mary dysplasia remained approx the same with increasing doses of DMBA (the 4.0-, 6.0-, and 9.0-mg treatments produced 27%, 30%, and 40% incidences, respectively), and mean number of dysplasias in non-tumor bearing mice was not significantly different from those in tumor-bearing animals. Nine transplantable outgrowth lines of dysplasia were established by transplantation of the primary lesion into the cleared mammary fat pads of syngeneic mice. When followed 6-9 generations in culture, most lines exhibited a rapid decline in growth potential. The 8/9 lines that extended throughout the mammary fat pads as ductal hyperplasias did not grow subcutaneously during the first few transplant generations. Thereafter, the lines either progressed to papillomatosis or carcinomas at varying rates (usually by transplant generation 7) died out, or remained stable as atypical ductal hyperplasias. The cell lines and mammary tumors established from urethane-induced hyperplasias were ovary-dependent for tumorigenesis and tumor growth. It appears that ductal hyperplasias have high tumorigenic potential and can be classified as "high-risk" lesions. (20 refs)

79-0859 Caffeine Inhibits Excision of 7-Bromomethylbenz(a)anthracene-DNA Adducts from Exponentially Growing but Not from Stationary Phase Chinese Hamster Cells. (Eng) Friedlos, F. (Chemical Carcinogenesis Div., Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Bucks HP8 4SP, England); Roberts, J. J. *Nucleic Acids Res* 5(12): 4795-4803; 1978.

Studies were carried out to determine whether the degradation of substituted template DNA seen in 7-bromomethylbenz(a)anthracene (7-BMBA)-damaged cells growing in a potentiating concentration of caffeine could reflect the first endonucleolytic step of a subsequently abortive attempt at excision repair. The effect of subtoxic concentrations of caffeine on the excision of 7-BMBA-DNA adducts from exponentially growing and from stationary, non-DNA-replicating cultures of Chinese hamster V79-379A cells was compared. Excision of 7-BMBA-DNA adducts from the exponentially growing cultures followed logarithmic kinetics, with a half-life of approx 20 hr. Posttreatment incubation in the presence of 0.75 mM caffeine markedly reduced this loss. Caffeine caused a concomitant increase in overall DNA synthesis rate in treated exponential cultures. Excision in stationary, non-DNA-replicating cultures was slower, and caffeine did not affect this reduced rate of excision. These findings support the hypothesis that the caffeine-induced inhibition of elongation of nascent DNA on a template containing chemi-

cal lesions results in an interference with the excision repair mechanism that removes these lesions. (21 refs)

- 79-0860 Alcohol and Hamster Buccal Pouch Carcinogenesis.** (Eng) Freedman, A. (Dept. Oral Medicine and Oral Pathology, Harvard Sch. Dental Medicine, 188 Longwood Ave., Boston, MA, 02115); Shklar, G. *Oral Surg* 46(6): 794-805; 1978.

The effect of alcohol consumption on the development of leukoplakia and epidermoid carcinoma induced by dimethylbenzanthracene (DMBA) was studied in the buccal pouch of the Syrian hamster. Forty animals were divided into four equal groups: Group I had the left buccal pouch painted with 0.5% DMBA soln 3 x/wk; Group II received the DMBA treatment plus 10% alcohol added to drinking water given ad libitum; the other two groups were the untreated and the alcohol-treated controls. Animals were sacrificed after 10, 12, or 14 wk of exposure. Group II animals developed leukoplakia, dysplasia, and well-differentiated papillary epidermoid carcinoma 2 wk before Group I. The tumors, which demonstrated surface necrosis and deep invasion of underlying connective tissue, were more numerous, larger, more extensive, and histologically more anaplastic in Group II animals. Furthermore, the liver of many Group II animals demonstrated a granular degeneration of parenchymal cell cytoplasm after 12 wk. Although the specific action of alcohol in this instance is not known, this study offers further evidence of its synergistic effect in enhancing the carcinogenicity of a locally applied agent. (22 refs)

- 79-0861 Tumor Promoter Induces Sister Chromatid Exchanges: Relevance to Mechanisms of Carcinogenesis.** (Eng) Kinsella, A. R. (Departement de Biologie Moleculaire, Universite Libre de Bruxelles, B 1640 Rhode-St-Genese, Belgium); Radman, M. *Proc Natl Acad Sci USA* 75(12): 6149-6153; 1978.

The cytogenetic effects of 12-O-tetradecanoylphorbol-13-acetate (TPA) on Chinese hamster cells in vitro were studied in order to test a hypothesis of tumor promotion. TPA (10 μ l/10 ml medium) induced sister chromatid exchanges (SCE), whereas the nonpromoting derivative 4-O-methyl-TPA did not. Antipain (1 mM), leupeptin (1 mM), and fluocinolone acetonide (1 μ g/ml), inhibitors of tumor promotion, all inhibited the formation of TPA-induced SCE. Because TPA induces several gene functions, it might also induce enzymes involved in genetic recombination. Thus, the irreversible step in tumor promotion might be the result of an aberrant mitotic segregation event leading to the expression of carcinogen/-mutagen-induced recessive genetic or epigenetic chromosomal changes. (33 refs)

- 79-0862 Disturbances of Early Sea-Urchin Development by the Tumor Promoter TPA (Phorbol Ester).**

(Eng) Bresch, H. (Abteilung fur Experimentelle Pathologie, Medizinische Hochschule, D-3000 Hannover, W. Germany); Arendt, U. *Naturwissenschaften* 65(12): 660-662; 1978.

The effect of 12-O-tetradecanoylphorbol-13-acetate (TPA) on the early sea urchin embryo was studied in order to determine whether the effects of this carcinogen are similar in mammalian and nonmammalian eucaryotic cells. Sea urchin morulae were incubated with different TPA concentrations, and incubation was continued until the pluteus stage. At 10^{-7} M, TPA blocked cleavage and caused cell lysis. At 10^{-8} M, the rate of cleavage was reduced and differentiation of the embryos proceeded abnormally, resulting in anomalous gastrulae. Differentiation of the gut and skeletal development were suppressed. At 10^{-9} M, TPA had less effect on development; some gut differentiation was seen with this dose, although the skeleton was rudimentary. Development appeared normal at concentrations of 10^{-10} M or less. The noncocarcinogenic phorbol derivatives 4-O-methyl-12-O-tetradecanoylphorbol-13-acetate and 12-O-acetylphorbol-13-acetate proved to be at least 100 times less harmful to the embryo than TPA. A third experiment demonstrated that incubation with TPA for only 1 hr caused the same abnormalities as did incubation from the morula to the pluteus stage. Since the embryotoxic effects of the three phorbol derivatives apparently run parallel to their cocarcinogenic activity, the mechanisms by which the cocarcinogen acts on mammalian and embryo cells may be similar. The sea urchin embryo may represent a useful model for elucidating the molecular action of phorbol esters in cells. (9 refs)

- 79-0863 Plasminogen Activator in Chick Embryo Muscle Cells: Induction of Enzyme by RSV, PMA and Retinoic Acid.** (Eng) Miskin, R. (Lab. Chemical Biology, Rockefeller Univ., New York, NY, 10021); Easton, T. G.; Reich, E. *Cell* 15(4): 1301-1312; 1978.

The induction of plasminogen activator (PA) in differentiating chick skeletal muscle cultures by Rous sarcoma virus (RSV), phorbol myristate acetate (PMA), and retinoic acid^x was studied. Unstimulated cultures spontaneously produced low levels of PA during myogenesis, peak activity appearing shortly after cell fusion. In cultures infected with the temperature-sensitive ts-68 mutant of RSV, PA activity was sevenfold higher at 41 C than in uninfected controls, a still greater increase in activity being evident in infected cultures at 37 C. PMA also induced PA activity in muscle cell cultures, max stimulation occurring 5 hr after exposure to 81-162 nanoM PMA. PMA also strongly inhibited the fusion of myoblasts into myotubes and altered the gross morphology of myotubes in cultures. There was no increase in DNA synthesis. Retinoic acid in the concentration range 10^{-8} to 10^{-5} M also stimulated PA synthesis in myogenic cultures. Dibutyryl cyclic (C) cAMP and cholera toxin weakly enhanced PA synthesis by myogenic cultures, but they profoundly depressed enzyme production by chick embryo fibroblasts. This suggests that enzyme induction by RSV and PMA is not mediated primarily via their effects on cAMP metabolism. (41 refs)

79-0867 Effects of the Tumor-promoting Agent 12-O-Tetradecanoylphorbol-13-acetate on Normal and "Preneoplastic" Mouse Submandibular Gland Epithelial Cells In Vitro. (Eng) Knowles, M. A. (Dept. Oncology, Middlesex Hosp. Medical Sch., London W1P 7PN, England). *J Natl Cancer Inst* 62(2): 349-352; 1979.

The effect of the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) was studied in mixed primary cultures of mouse submandibular gland and in slowly proliferating preneoplastic epithelial foci derived from these cultures. The primary cultures received one of the following treatments: (1) 0.05% dimethyl sulfoxide for 24 hr on days 4-5 of culture [DMSO(a)] followed by 0.05% DMSO for 72 hr weekly [DMSO(b)]; (2) DMSO(a) followed by weekly 0.05 µg/ml TPA + DMSO(b); (3) 0.1 µg/ml 7,12-dimethylbenz(a)anthracene (DMBA) + DMSO(a) followed by DMSO(b); and (4) 0.1 µg/ml DMBA + DMSO(a) followed by 0.05 µg/ml TPA + DMSO(b). During the first 30 days, TPA-treated cultures were indistinguishable from the others. The development of three-dimensional epithelial ducts, which was seen at 30-60 days in the cultures not treated with TPA, was markedly inhibited in TPA-treated cultures. At 100 days, the incidence of slow-growing foci in cultures treated with DMBA/DMSO/TPA was 4.24/100 explants (after correction for DMBA-induced toxicity). The corresponding number of foci in the other cultures was 1.40 for DMSO/DMBA, 0.86 for DMSO/DMSO, and 0.79 for DMSO/TPA. TPA had no effect on the emergence of tumorigenic cell lines at a late stage in culture (150 days) or on the development of such lines from nine preexisting foci derived from non-TPA-treated cultures. Epithelial proliferation, as shown by the ³H-thymidine labeling index and mitotic index, seemed to increase during treatment with TPA and then to fall between the weekly treatments. The finding of both tumor promotional activity and an effect on cell differentiation for TPA suggests that the two are related. (16 refs)

79-0868 Stimulation of the Synthesis of the H1 and H3 Histone Fractions of Mouse Epidermis by 12-O-Tetradecanoylphorbol-13-acetate. (Eng) Raineri, R. (McArdle Lab. Cancer Res., Univ. Wisconsin Medical Center, Madison, WI, 53706); Simsiman, R. C.; Boutwell, R. K. *Cancer Lett* 5(5): 277-284; 1978.

In this two-part study, epidermal histones from female CD-1 mice were fractionated chemically and separated electrophoretically, and incorporation of isotopically labeled precursor into specific histone fractions was determined following treatment of mice with 12-O-tetradecanoylphorbol-13-acetate (TPA). The five fractions resulting from chemical treatment were subjected to acrylamide gel electrophoresis (EP) at pH 3.2 using 15% gels. Their migration sequence was the same as that reported for calf thymus histones. Parallel EP of unfractionated histone extract confirmed identification of the five bands as the H1, H4, H3, H2B, and H2A histone fractions. In the second study, 17 nanomoles of TPA in acetone were applied to the shaved back skin of mice 24 hr before sacrifice; they were inoculated ip with 100 µCi ³H-lysine 1 hr before sacrifice. Aliquots from the crude histone extract were subjected to cellulose acetate and acrylamide gel EP. TPA increased the incorporation of lysine into epidermal histone fivefold, and the histone extract contained five major electrophoretic bands regardless of pretreatment with TPA. Compared with histone bands from control mice, there were large increases in ³H-lysine incorporation into H1 and H3 and smaller but significant increases in incorporation into H2B, H2A, and H4. The amount of ³H-lysine incorporated was not related to the quantity of each histone, in spite of the fact that histone synthesis was previously found to be coupled to DNA synthesis in mouse skin epidermis. The relationship of histone to DNA may be altered by certain phorbol esters, a suggestion that is compatible with the concept that gene activation is the decisive function of these esters in tumor formation. (18 refs)

79-0869 Comparison of Benzo(a)pyrene Metabolism by Human Peripheral Blood Lymphocytes and Monocytes. (Eng) Vaught, J. B. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., Buffalo, NY, 14263); Gurtoo, H. L.; Paigen, B.; Minowada, J.; Sartori, P. *Cancer Lett* 5(5): 261-268; 1978.

An improved, sensitive, high-pressure liquid chromatography (HPLC) assay of benzo(a)pyrene (BP) metabolites was used to examine the profiles elaborated by human lymphocytes and monocytes. As little as 10 x 10⁶ cells and only 1 hr incubation with BP were required. Human lymphocytes and monocytes in culture were exposed to 10 µM benz(a)anthracene 24 hr before harvest to induce aryl hydrocarbon hydroxylase (AHH) activity. The cells from these induced cultures were then incubated with ³H-BP (0.1 µCi micromole) for 1 hr and then analyzed by HPLC. Both cell types produced primarily 3-hydroxy-BP, 9-hydroxy-BP, quinones, and dihydrodiols, particularly, 7,8-dihydrodiol. The

lymphocytes also produced a peak slightly more polar than the marker 9,10-dihydrodiol peak. Addition of 1,1,1-trichloropropene oxide (10^{-3} M) to the reaction mixture resulted in loss of the 7,8-dihydrodiol peak in both cell types. α -Naphthoflavone (10^{-3} M), an inhibitor of polycyclic aromatic hydrocarbon-inducible cytochrome, caused an overall decrease in BP metabolism. Since diol epoxides at the 7,8,9,10-positions of BP have been postulated as the ultimate carcinogen metabolites, the production of 7,8-dihydrodiol by both monocytes and lymphocytes is significant in indicating the likely potential of human tissues to activate BP. (29 refs)

79-0870 Enzymic Formation of Free Radical from Anthanthrene and 10-Azabenz[a]pyrene Lacking the Bay Region. (Eng) Kodama, M. (Biophysics Div., National Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-Ku, Tokyo 104, Japan); Kimura, T.; Nagata, C.; Shudo, K. *Gann* 69(6): 865-866; 1978.

The enzymatic formation of free radicals from aromatic hydrocarbons lacking the bay region was studied by electron spin resonance. Incubation of anthanthrene with liver microsomes from methylcholanthrene-treated rats yielded a free radical with a g-value of 2.005 and a linewidth of 9.8 gauss. The free radical was tentatively identified as the semiquinone radical. The free radical formed from 10-azabenz(a)pyrene had a g-value of 2.004 and a linewidth of 14.3 gauss; it was tentatively identified as 6-oxy-10-azabenz(a)pyrene. The two free radicals bound covalently with polyguanylic acid, retaining their free radical forms. The data indicate that the formation of a free radical is involved in the activation process of anthanthrene and 10-azabenz(a)pyrene. (7 refs)

79-0871 Methylcholanthrene Induced Murine Primitive Neuroectodermal Tumor: Ultrastructure and Nuclear RNA Polymerase Activity. (Eng) Slagel, D. E. (Lab. Neurochemistry, Div. Neurosurgery, Dept. Surgery, Univ. Kentucky Coll. Medicine, Lexington, KY, 40506). *Acta Neuropathol (Berl)* 44(3): 173-182; 1978.

Examination was made of the histology, ultrastructure, and nuclear RNA polymerase activity of a murine primitive neuroectodermal tumor derived by serial transplantation from an experimental ependymoblastoma induced by methylcholanthrene. Morphologically, the tumor consisted of cuboid cells with pleomorphic nuclei often arranged in rosettes, but the usual polarity seen in an ependymoma rosette was lacking. The nuclei contained 1-10 large nucleoli. Ultrastructurally, the cells forming the rosette pattern lacked the apical and basal regions found in ependymoma cells. Desmosomes and zonula occludens were not observed. The most prominent ultrastructural feature was irregularly lobulated nuclei. A-type virus particles were seen in the cytoplasm, and B-type virus particles were seen budding into the extracellular space. The nuclear RNA synthesizing activity was very high

(guanosine triphosphate incorporation, 0.22 nanomole/mg DNA/hr). α -Amanitin and adriamycin inhibited RNA synthesis in the tumor nuclei by 42% and 58%, respectively. The ultrastructure of the tumor suggests that a large part of nuclear RNA synthesis may be carried out by RNA polymerase I in the nucleoli of the tumor cells. (73 refs)

79-0872 Metabolic Activation of 3-Methylcholanthrene: Mutagenic and Transforming Activities of the 9,10-Dihydrodiol. (Eng) Malaveille, C. (International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon, France); Bartsch, H.; Marquardt, H.; Baker, S.; Tierney, B.; Hewer, A.; Grover, P. L.; Sims, P. *Biochem Biophys Res Commun* 85(4): 1568-1574; 1978.

3-Methylcholanthrene (3-MC) and five related dihydrodiols were tested for microsome-mediated mutagenicity toward *Salmonella typhimurium* TA100, for the induction of mutation to 8-azaguanine resistance in V79 Chinese hamster cells, and for malignant transformation in M2 mouse fibroblasts. In both mutagenicity test systems, trans-9,10-dihydro-9,10-dihydroxy-3-methylcholanthrene was considerably more active than 3-MC and cis-2 α ,3-dihydroxy-, trans-4,5-dihydro-4,5-dihydroxy-, trans-7,8-dihydro-7,8-dihydroxy-, and trans-11,12-dihydro-11,12-dihydroxy-3-MC. At 1 μ g/ml medium, the 9,10-diol induced the formation of more transformed malignant foci in cultures of M2 cells than 3-MC, but at higher and lower concentrations this difference was not apparent. The other diols were either inactive or only weakly active in this test system. Cells transformed by the 9,10-dihydrodiol yielded tumors on injection into C3H/HeJ mice. These results are consistent with the hypothesis that the metabolic activation of 3-MC involves metabolism in the 7,8,9,10-ring and that this activation proceeds through formation of the 9,10-diol and its subsequent conversion into the related vicinal diol-epoxide, 9,10-dihydro-9,10-dihydroxy-3-methylcholanthrene 7,8-oxide, a bay region diol-epoxide. (16 refs)

79-0873 Changes in Cell Population Kinetics During Epidermal Carcinogenesis. (Eng) Fukuda, M. (Dept. Pathology, Kyoto Prefectural Univ. Medicine, Kawaramachi, Hirokoji, Kami-Kyoku, Kyoto, Japan); Okamura, K.; Rohrbach, R.; Bohm, N.; Fujita, S. *Cell Tissue Kinet* 11(6): 611-621; 1978.

Changes in cell population kinetics in response to wounding were compared in the hyperplastic epidermis (HE), papillomas, squamous cell carcinomas, and normal tissue of male dd mice. The HE and the tumors were induced by topical applications of 20-methylcholanthrene (0.5% soln) on shaved dorsal epidermis 2x/wk for up to 20 wk. In wounding experiments, a linear incision was made by a razor blade down to underlying muscle layers. Flash (in wounding experiments) or continuous DNA labeling with tritiated thymidine was

used for cell-cycle analyses. G_0 cells were absent in the HE, papillomas, and carcinomas. In HE, the proliferating cells (PC's) were localized in the basal layer. The PC zone was enlarged in the papillomas compared with that in normal or HE, but it was still localized in several layers above the basement membranes. PC's were distributed throughout most of the carcinoma tissue. The continuous labeling curves for HE and the tumors increased almost linearly and reached 100%, indicating the absence of heterogeneous cell subpopulations. Normal responses to wounding were preserved in the HE; ie, shortening of cell-cycle time and reversible enlargement of the PC zone were still observed, in spite of the absence of G_0 cells. These responses were not seen in the tumors; ie, flexible mechanisms controlling irreversible cell differentiation to mature cells and the duration of the cell cycle were lacking. In both tumors, the irreversible differentiation to mature cells also seemed fixed at a quantitatively low level in the PC's, because the PC zone was enlarged irreversibly, without showing any response to wounding. With the fixed probability of cell differentiation at a decreased level, the PC population in the tumor tissues will continue to grow larger and larger, in spite of the fixed prolongation of the cell cycle. (27 refs)

79-0874 Two-stage Malignant Transformation in Hamster Embryo Cells. (Eng) Poiley, J. A. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Raineri, R.; Pienta, R. J. *Br J Cancer* 39(1): 8-14; 1979.

The ability of 3-methylcholanthrene (MCA), 12-O-tetradecanoylphorbol-13-acetate (TPA), and/or dibenz(a,h)anthracene (DBA) to induce transformation in primary hamster embryo cells was studied. In cells treated with MCA or MCA + TPA, morphological transformation occurred at the same time regardless of treatment. Cells treated with MCA alone produced rapidly growing colonies in soft agar and induced more tumors in hamsters with a slightly shorter latent period, compared with cells treated with MCA + TPA. When TPA was administered simultaneously with or 7 days after MCA, transformation, growth in soft agar, and the ability to induce tumors were inhibited. Treatment with TPA 27 days after MCA reduced the latent period to morphological transformation and increased the ability of the cells to induce tumors. A promoting effect was found when cells treated with a subtransforming dose of DBA followed 7 to 30 days later by TPA. The data indicate that TPA acts as an inhibitor or promoter, depending on the length of time between carcinogen treatment and TPA administration. (12 refs)

79-0875 Changes in the Synthesis of Normal Antibodies to One of the Common Enterobacterial Antigens During the Carcinogenesis in Rats and Oncogenesis in Humans. (Rus) Montsevichiute-Eringene, E. V. (Res. Inst. Oncology, Vilnius, USSR). *Vestn Akad Med Nauk SSSR* (12): 69-71; 1978.

The normal level of antibodies to the common enterobacterial antigen (CEBA) was used for evaluation of the immunological status of Wistar rats with induced tumors and of people with subgastritis and achlorhydria and cancer. The rats were inoculated sc with 3-methylcholanthrene (MC: 5 mg) or with benzo(a)pyrene (BP: 1 mg) in peach kernel oil. Administration of the carcinogens resulted in a period of primary stimulation of antibody synthesis (62% of the sera from 4- to 5-mo-old treated rats contained antibodies, compared with 14% of the sera from nontreated rats), followed by a period of immunodepression (66% of the sera did not contain normal antibodies) and a period of secondary immunostimulation (during the last 5 wk of the experiment, when all rats developed tumors, 76% of the sera contained antibodies). At prophylactic examinations of patients, normal antibodies to CEBA could be detected in 33% of the individuals, compared with 46% of the patients with achlorhydria and 72.1% of the patients with cancer. (3 refs)

79-0876 Chemical Carcinogenesis in Nude Mice: Comparison Between Nude Mice from Homozygous Matings and Heterozygous Matings and Effect of Age and Carcinogen Dose. (Eng) Stutman, O. (Cellular Immunobiology Section, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021). *J Natl Cancer Inst* 62(2): 353-358; 1979.

The incidence and latency periods for local tumor development after injection of 3-methylcholanthrene (3-MC: 0.10, 0.01, 0.02, 0.05, or 0.10 mg sc) were compared in 30-day-old nude mice (nu/nu partially inbred on the CBA/H background) derived from homozygous (nu/nu x nu/nu) or heterozygous matings (nu/+ x nu/+). At these doses, neither tumor incidence nor latency period differed between the two groups of nude mice or between these mice and immunologically normal controls. This result was also observed when wt-adjusted doses of 3-MC equivalent to 0.02 or 0.10 mg in the 30-day-old mice were given at 120, 210, or 360 days of age. However, an age effect was observed, since tumor incidence decreased in nude and normal mice when 3-MC was administered at 210 and 360 days of age, especially in mice inoculated with the lower dose of 3-MC. 3-MC doses of 0.01-0.05 mg had no detectable immunosuppressive effects on normal mice. These findings indicate that the lack of differences in tumor incidence or latency periods between nude and normal mice following 3-MC administration cannot be ascribed to putative thymus function in nude mice bred from heterozygous parents, carcinogen dose, immunodepressive effects of the carcinogen, or age of the animals at the time of carcinogen administration. The results corroborate previous findings that nude mice do not show an increased risk for tumor development after exposure to 3-MC. (53 refs)

79-0877 Synthesis of the Dihydrodiols and Diol Epoxides of Benzo(e)pyrene and Triphenylene. (Eng) Harvey, R. G. (Ben May Lab. Cancer Res., Univ. Chicago,

Chicago, IL, 60637); Lee, H. M.; Shyamasundar, N. *J Org Chem* 44(1): 78-83; 1979.

Synthesis of the "bay region" dihydrodiols of benzo(e)pyrene and triphenylene and the corresponding anti-isomeric diol epoxides is described. Nuclear magnetic resonance analysis indicated that all four chemicals exist preferentially in the diaxial conformation. Both diol epoxides, derived from hydrocarbons inactive as carcinogens, were inactive as inhibitors of the ϕ X 174 DNA virus, whereas the analogous *anti*-diol epoxide of benzo[a]pyrene was highly potent. (35 refs)

79-0878 Molecular Calculations with the Nonempirical ab initio MODPOT, VRDDO, and MODPOT/VRDDO Procedures. IX. Carcinogenic Benzo(a)pyrene and its Metabolites Using a MERGE Technique. (Eng) Kaufman, J. J. (Dept. Anesthesiology, John Hopkins Univ. Sch. Medicine, Baltimore, MD, 21205); Popkie, H. E.; Palalikit, S.; Hariharan, P. C. *Int J Quantum Chem* 14(6): 793-800; 1978.

Quantum chemical calculations were carried out on benzo(a)pyrene (BP) and its dihydrodiol and dihydrodiol epoxide metabolites. Computations were carried out using two programs: ab initio effective core model potentials (MODPOT) and variable retention of diatomic differential overlap (VRDDO). A new MERGE technique allowing reuse of integrals of a common skeletal fragment was also utilized. Preliminary calculations indicated the β,β,β conformation of BP-7,8-dihydrodiol-9,10-epoxide to be the most stable of the geometries tested. The data also confirmed the hypothesis that the epoxide ring opening in this compound would favor the O remaining on C₉ rather than C₁₀. The total energy corresponding to opening the ring to a 90 degree angle O-C₉-C₁₀ is lower than for opening the ring to a 90 degree angle O-C₉-C₈. The lowest energy surface for opening the epoxide ring to a 90 degree C₁₀-C₉-O angle leads to a slightly more negative change on the C₁₀ (-0.20) than when the epoxide ring is completely closed (-0.12). As the ring is opened past a 90 degree O-C₉-C₁₀ or O-C₁₀-C₉ angle, there is some indication that there may be a mixing of configurations. (13 refs)

79-0879 Effects of Benzo(a)pyrene Adducts on DNA Synthesis In Vitro. (Eng) Yamaura, I. (Sloan-Kettering Inst. Cancer Res., Walker Lab., 145 Boston Post Road, Rye, NY, 10580); Marquardt, H.; Cavalieri, L. F. *Chem Biol Interact* 23(3): 399-407; 1978.

The diol epoxide derivatives of the polycyclic aromatic hydrocarbon benzo(a)pyrene (BP), (\pm)-7 β ,8 α -dihydroxy-9 β ,10 β -epoxy-7,8,9,10-tetrahydro BP, and (\pm)-7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydro BP (*cis* and *trans* isomers, respectively), have been used to make adducts in the homopolymers polyribocytidylic acid, polydeoxycytidylic acid, polyriboadenylic acid, and polydeoxyadenylic acid. In

conjunction with appropriate oligomers as primers, these polynucleotides were used as templates for DNA synthesis with avian myeloblastosis virus DNA polymerase or *Escherichia coli* Pol I DNA polymerase. Results revealed that the size of the DNA product is not significantly decreased by the presence of these adducts in the template. Furthermore, the presence of these adducts does not lead to increased incorporation of erroneous bases. This evidence, coupled with kinetic data, suggests that these polymerases can bypass a site containing an adduct on the template without leaving a gap or causing misincorporation of a base. It is concluded that mutagenesis by BP may not be attributable to either of these mechanisms. (28 refs)

79-0880 Comparison of In Vivo and In Vitro Binding of Polycyclic Hydrocarbons to DNA. (Eng) Eastman, A. (Dept. Biochemistry, Univ. Vermont Coll. Medicine, Burlington, VT, 05405); Sweetenham, J.; Bresnick, E. *Chem Biol Interact* 23(3): 345-353; 1978.

The in vivo binding of ³H-benzo(a)pyrene (BP) and ³H3-methylcholanthrene (3MC) to liver and lung DNA was studied in A/J mice. Only in liver was there any reduction in total DNA-bound radioactivity between 4 and 24 hr after hydrocarbon administration. DNA was fractionated on Sephadex LH-20 after enzymatic digestion. A single deoxyribonucleoside-BP adduct was detected, but two major 3MC-adducts were observed. With both BP and 3MC, three additional peaks of radioactivity eluted rapidly in the lung DNA experiments and a fourth was noted with liver DNA. The nucleoside-bound adducts from lung represented a much larger proportion of the total radioactivity than did those from liver. In vitro analysis of 3MC binding to DNA showed that the nucleoside-bound adducts were predominantly deoxyguanosine-dependent; however, the early peaks were independent of base, suggesting binding to another part of the DNA molecule, perhaps phosphate, ie, phosphotriesters. The higher proportion of aryl alkylated nucleosides in the lung may be related to the susceptibility of this organ to polycyclic hydrocarbon-induced carcinogenesis. (32 refs)

79-0881 Effects of Microsomal Enzyme Inducers In Vivo and Inhibitors In Vitro on the Covalent Binding of Benzo(a)pyrene Metabolites to DNA Catalyzed by Liver Microsomes from Genetically Responsive and Nonresponsive Mice. (Eng) Boobis, A. R. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014); Nebert, D. W.; Pelkonen, O. *Biochem Pharmacol* 28(1): 111-121; 1979.

Increases or decreases in nine benzo(a)pyrene (BP) metabolite-nucleoside peaks caused by the use of various microsomal enzyme inducers in vivo and inhibitors in vitro were examined with respect to genetically responsive or nonresponsive mice, in an attempt to understand and identify changes in

reactive BP intermediates that bind to DNA. The peaks were named A (most polar) through I (least polar). 3-Methylcholanthrene (3-MC), 2,3,7,8-tetrachlorodibenzo-p-dioxin, phenobarbital, Aroclor 1254, pregnenolone-16 α -carbonitrile, or ethanol was administered in vivo to responsive C57BL/6N or nonresponsive DBA/2N mice. The rises or falls in the peaks were noted when liver microsomes from control or 3-MC-treated C57BL/6N or DBA/2N mice were incubated with ³H-BP and microsomal enzyme inhibitors. All interpretations concerning the binding of metabolites to DNA were consistent with non-K-region oxygenation of BP being mediated predominantly by cytochrome(s) P₁-450 and K-region oxygenation of BP being catalyzed predominantly by form(s) of P-450 other than P₁-450. All biological perturbations were consistent with the following assignments. The major reactive intermediate of BP contributing to each peak was suggested to be: peaks A and C, an unknown dihydrodiol oxide; peaks B, D, F, and I, quinones oxygenated further (or quinone-derived free radicals); peak E, both cis- and trans-7,8-diol-9,10-epoxides; peak F', the 7,8-oxide; peak G, the 4,5-oxide; and peak H, an unknown phenol oxide. The major metabolite(s) contributing to all peaks except F' and G involve(s) more than a single monooxygenation by forms of cytochrome P-450. All peaks except G appear to be predominantly associated with BP metabolism mediated by P₁-450 and, therefore, controlled by the *Ah* locus. The use of these microsomal inducers or inhibitors--combined with the underlying genetic predisposition of the individual, tissue, or cell culture system under study--demonstrates that the balance between P-450 and epoxide hydase and the ratio of each form of P-450 to the other forms of P-450 can influence markedly the quantity and quality of reactive intermediates of BP that bind to DNA. (43 refs)

79-0882 Fluorescence Study of DNA-Complexes Formed after Metabolic Activation of Benzo(a)-pyrene Derivatives. (Eng) Dock, L. (Dept. Forensic Medicine, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Undeman, O.; Graslund, A.; Jernstrom, B. *Biochem Biophys Res Commun* 85(4): 1275-1282; 1978.

Several benzo(a)pyrene (BP) phenols and dihydrodiols were incubated with liver microsomes obtained from 3-methylcholanthrene-treated rats and calf thymus DNA for 30 min. The modified DNA, native or denatured, was assayed by fluorescence for bound metabolites. Of the derivatives tested, only 2-hydroxybenzo(a)-pyrene (2-OH-BP), 9-hydroxybenzo(a)-pyrene (9-OH-BP), and trans-7,8-dihydro-7,8-dihydroxybenzo(a)pyrene (BP 7,8-dihydrodiol) yielded detectable amounts of DNA-bound products. 1-Hydroxy-, 3-hydroxy-, 7-hydroxy-, trans-9,10-dihydro-9,10-dihydroxy-, and trans-4,5-dihydro-4,5-dihydroxy-BP did not give detectable DNA-bound products. In contrast to the product(s) from 9-OH-BP, the metabolites of 2-OH-BP and BP 7,8-dihydrodiol, both strong carcinogens, had similar excitation spectra. The fluorescence intensity associated with products of BP 7,8-dihydrodiol and 2-OH-BP was enhanced severalfold

after denaturation of DNA, but denaturation of DNA modified by products from 9-OH-BP resulted in a 50% reduction of the fluorescence intensity. These data indicate that there are structural similarities in the DNA complexes formed after metabolic activation of 2-OH-BP and BP 7,8-dihydrodiol. The results with 9-OH-BP also indicate that DNA binding alone is not sufficient for carcinogenicity. Factors such as the structures of the DNA-binding intermediate and the subsequent DNA complex must also be considered. (23 refs)

79-0883 Mutagenic Substances as Possible Senility Factors. (Eng) Sirtori, C. (Multiscreening Lab., Gaslini Inst., Genoa, Italy); Paganuzzi, M.; Lombardo, C.; Scalese, S.; Ruzzon, T. *Pharmacol Res Commun* 10(9): 809-912; 1978.

The results of several varied studies are reported briefly. The urine of 11/12 smokers was positive in the Ames Salmonella mutagenicity assay; that of 12/12 nonsmokers was negative. Thin-layer chromatography showed that benzo(a)pyrene (BP) is present in higher amounts in the urine of nonsmokers, but probable BP metabolites are present only in the urine of smokers. Routine use of contraceptive ovuli (not pills) containing anti-inflammatory substances may have anti-cervical cancer properties and antimutagenic properties in spermatocytes. Mutagenic or carcinogenic agents are also factors that favor senility. (9 refs)

79-0884 Induction, Modification and Inhibition of Rat Liver Microsomal Benzo(a)pyrene Hydroxylase; Correlation with the S-9-Mediated Mutagenicity of Benzo(a)pyrene. (Eng) Razzouk, C. (Lab. Biotoxicology, Univ. Louvain, Sch. Pharmacy, U.C.L.-73.69, B-1200 Brussels, Belgium); Agazzi-Leonard, E.; Cumps, J.; Poncelet, F.; Mercier, M.; Roberfroid, M. *Biochem Biophys Res Commun* 85(3): 1007-1016; 1978.

The effects of various pretreatments in vivo and of various inhibitors in vitro on the activity of rat liver microsomal benzo(a)pyrene hydroxylase were analyzed and correlated with the liver microsome (S-9)-mediated mutagenicity of benzo(a)-pyrene (BP) to *Salmonella typhimurium* strain TA1538. Adult male Wistar rats were treated with phenobarbital (PB), 3-methylcholanthrene, (3-MC), 2-fluorenylacetylamide (2FAA), or 4-fluorenylacetylamide (4AAF) before preparation of the liver microsomal fraction. At a low concentration of both proteins (4.3 μ g/ml) and BP (0.05-2 μ M), the V_{max} and K_m of the BP hydroxylase from 3-MC-treated rats were 2.4 times higher and 10 times lower than the same parameters of control enzymatic preparations, indicating that 3-MC induced (V_{max}) and modified (K_m) the enzyme activity. 3-MC pretreatment also increased the enzyme-mediated mutagenicity. Pretreatment with PB or 2FAA did not induce or modify BP hydroxylase and did not increase the S-9-mediated mutagenicity of BP. Of the various inhibitors

tested, only Miconazole inhibited all the tested microsomal preparations and reduced S-9-mediated mutagenicity. The inhibitory effects of 7,8-benzoflavone and SKF525A were limited to enzyme preparations from 3-MC-induced and control or PB-induced rats, respectively. Thus, rat liver microsomal BP hydroxylase induction and modification correlate with the S-9-mediated mutagenicity of BP. (22 refs)

- 79-0885 Base Specificity in the Binding of Benzo(a)pyrene Diol Epoxide to Simian Virus 40 DNA.** (Eng) Mengle, L. (Lab. Chemical Biodynamics, Lawrence Berkeley Lab., Univ. California, Berkeley, CA, 94720); Gamper, H.; Bartholomew, J. *Cancer Lett* 5(3): 131-137; 1978.

The simian virus 40 (SV40) DNA molecule, isolated from SV40-infected TC-7 African green monkey kidney cells, was used to assess the effect of the structure of DNA on its binding to 7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene (BP diol epoxide). ¹⁴C-SV40 DNA (2.5 μ g) and ³H-BP-diol epoxide (0.013-0.13 μ g) were incubated for 24 hr, and the modified DNA was digested to completion with 10 units of Hind III restriction endonuclease. The six characteristic fragments that resulted were separated by polyacrylamide gel electrophoresis. Binding of BP diol epoxide was proportional to the molar ratio of hydrocarbon to DNA in the reaction mixture. In subsequent experiments, SV40 DNA was reacted with the diol epoxide at a molar ratio of 7.0×10^{-3} , thereby inducing 0.60 adduct/molecule of DNA. This level of adduct formation was approx that seen in vivo and it had no effect on Hind III digestion. The extent of adduct formation was not strictly dependent on DNA length, and this appears to reflect variability in the guanine-cytosine (G-C) content of the fragments. Hydrocarbon binding to the fragments was proportional to their G-C content, reflecting selective reaction of the hydrocarbon with deoxyguanosine residues. Despite the low level of modification, no sites unusually susceptible to alkylation were detected. (18 refs)

- 79-0886 Comparison of the In Vitro Mutagenicity and Metabolism of Dimethylnitrosamine and Benzo(a)pyrene in Tissues from Inbred Mice Treated with Phenobarbital, 3-Methylcholanthrene or Polychlorinated Biphenyls.** (Eng) Hutton, J. J. (Medical Services, VA Hosp., Lexington, KY, 40507); Meier, J.; Hackney, C. *Mutat Res* 66(1): 75-94; 1979.

Homogenates of liver, lung, kidney, stomach, small intestine, and colon from eight mouse strains were compared for their ability to metabolize benzo(a)pyrene (BP) and dimethylnitrosamine (DMN) to mutagens. CF1, AKR/J, AU/SsJ, DBA/2J, SWR/J, A/J, C3H/HeJ, and C57BL/6J females were untreated or inoculated ip with phenobarbital (PB), 3-methylcholanthrene (MC), or Aroclor 1254 (AR) prior to

sacrifice. Mutagenesis was detected using *Salmonella typhimurium* TA92 and TA98. AR and MC were good inducers of aryl hydrocarbon hydroxylase (AHH) activity in liver from aromatic hydrocarbon-responsive strains, but not in liver from nonresponsive strains. Metabolism of BP to mutagens by liver homogenates was correlated with extent of AHH induction. Basal activities of AHH and dimethylnitrosamine demethylase (DMND) were correlated in liver and lung from untreated mice. DMND activities were increased less than twofold by PB, MC, or AR. Livers from untreated mice converted DMN and BP to mutagens, but there was no significant quantitative correlation between DMND activity and DMN mutagenesis or between AHH activity and BP mutagenesis. Conversion of DMN and BP to mutagenic metabolites could not be detected in homogenates from kidney, stomach, small intestine, or colon. These studies indicate that mouse strain, organ, and test substance are important variables in assessing the potential effect of microsomal enzyme-inducing agents on the metabolism of mutagens. (45 refs)

- 79-0887 Mutagenicity and Cytotoxicity of Light-activated Procarcinogens (Meeting Abstract).** (Eng) Barnhart, B. J. (Los Alamos Scientific Lab., Univ. of California, Los Alamos, NM, 87545); Cox, S. H.; Okinaka, R. T. *J Cell Biol* 79(2, part 2): 388a; 1978. (no refs)

- 79-0888 Effect of Chronic Ethanol Ingestion on Intestinal Metabolism and Mutagenicity of Benzo(a)pyrene.** (Eng) Seitz, H. K. (Alcoholism Res. and Treatment Center, Bronx V.A. Hosp., New York, NY); Garro, A. J.; Lieber, C. S. *Biochem Biophys Res Commun* 85(3): 1061-1066; 1978.

The effect of chronic ethanol ingestion on intestinal microsomal cytochrome P-450 level, benzo(a)pyrene hydroxylase activity, and activation of benzo(a)pyrene (BP) to a mutagen was studied in male Sprague-Dawley rats. The rats were fed a diet containing 36% of total calories either as ethanol or as isocaloric carbohydrates for 3-4 wk before sacrifice. There was a threefold increase in intestinal microsomal cytochrome P-450 level in the ethanol-fed rats compared with that in the controls [26.0 vs 8.9 picomoles (pmol)/mg microsomal protein]. Intestinal BP hydroxylase activity was also increased threefold in the ethanol-fed rats (18.1 vs 6.6 pmol 3-hydroxy-BP/mg microsomal protein/min). When BP was tested for mutagenic activity to *Salmonella typhimurium* strain TA100 in the presence of microsomes from ethanol-fed and control animals, clear dose-response curves were observed. Over the entire range of BP concentrations studied, the levels of revertants were highest with microsomes of ethanol-fed animals. The results suggest that the increased incidence of cancer among alcoholics may be due to the enhanced capacity of these individuals to activate procarcinogens in the intestine. (25 refs)

79-0889 Benzo(a)pyrene-initiated Leukemia in Mice: Association with Allelic Differences at the *Ah* Locus. (Eng) Nebert, D. W. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014); Jensen, N. M. *Biochem Pharmacol* 27(1): 149-151; 1979.

The induction of leukemia by benzo(a)pyrene (BP) was studied in mice responsive (*Ah^b*) and nonresponsive (*Ah^d*) to the induction of cytochrome P₁-450 and P-448 and monooxygenase activities by polycyclic aromatic hydrocarbons. Groups of 30 nonresponsive *Ah^d/Ah^d* or responsive *Ah^b/Ah^d* mice were given 12 or 6 mg BP/kg/day po. At 12 mg/kg/day, all *Ah^d/Ah^d* mice died before 110 days on the diet; none of the 30 *Ah^b/Ah^d* had died by day 100; 3 died after 150 days. At 6 mg/kg/day, 24/30 *Ah^d/Ah^d* mice and 2/20 *Ah^b/Ah^d* mice had died after 240 days on the diet. Mice that became ill and died did not have the expected hypoplastic or aplastic bone marrow but rather developed hematopoietic neoplasms, especially of the lymph nodes, spleen, and thymus. When α -naphthoflavone (ANF) was added to the diet at a dose 20 times greater than that of BP (6 mg/kg/day), the incidence of leukemia was prevented almost completely and the general health of the *Ah^d/Ah^d* mice remained as good as that of the *Ah^b/Ah^d* mice receiving 12 mg BP/kg/day. These data suggest that the ANF-sensitive metabolism of BP, presumably mediated by cytochrome P₁-450 in the bone marrow of *Ah^d/Ah^d* mice, is responsible for the reticuloendothelial malignancies. These results may be explained on the basis of "first-pass elimination" kinetics. (13 refs)

79-0890 UDP-Glucuronosyl Transferase and the Conjugation of Benzo(a)pyrene Metabolites to DNA. (Eng) Fahl, W. E. (Dept. Pharmacology, Univ. Wisconsin Medical Sch., Madison, WI, 53706); Shen, A. L.; Jefcoate, C. R. *Biochem Biophys Res Commun* 85(3): 891-899; 1978.

The role of uridine diphosphate (UDP)-glucuronosyl transferase in the conjugation of benzo(a)pyrene (BP) metabolites to DNA was studied. Following the addition of UDP-glucuronic acid (UDPGA) to incubations containing ³H-BP and liver microsomes from methylcholanthrene-induced rats, there were large decreases in the levels of BP quinones and 3-phenol, which were half max at 1.0 and 1.6 mM UDPGA, respectively. The 9-phenol was less sensitive to UDPGA. Total BP metabolism increased maximally (by 38%) at 2 mM UDPGA. Treatment of the water-soluble incubation products with β -glucuronidase followed by organic extraction and high-pressure liquid chromatographic analysis of the extract and quantification of the released compounds indicated that the mixed function oxidation of BP is stimulated unselectively in the presence of 2 mM UDPGA. In the presence of calf thymus DNA, UDPGA caused a 2.7-fold increase in the conjugation of benzo(a)pyrene 7,8-dihydrodiol 9,10-oxide to DNA. Max DNA modification by the diol-oxides occurred at a UDPGA concentration (2 mM) that gave the highest level of free BP 7,8-dihydrodiol. The UDPGA-induced in-

crease in BP oxidation and concomitant increase in diol-oxide modification of DNA is consistent with the removal of product inhibition by glucuronide conjugation of an inhibitory BP metabolite. It seems, therefore, that although UDPGA and glucuronosyl transferase decrease the modification of DNA, which has been attributed to phenol-oxides, this enzyme activity may increase the carcinogenicity of BP by relieving product inhibition of cytochrome P-450. (20 refs)

79-0891 Application of CNDO/2 Theoretical Calculations to Interpretation of the Chemical Reactivity and Biological Activity of the *Syn* and *Anti* Diol Epoxides of Benzo(a)pyrene. (Eng) Yeh, C. Y. (Dept. Chemistry, Soochow Univ., Shihlin, Taipei, Taiwan, Republic China); Fu, P. P.; Beland, F. A.; Harvey, R. G. *Bioorg Chem* 7(4): 497-506; 1978.

CNDO/2 molecular orbital theoretical calculations were performed on the anti and syn diol epoxides (DE's) of benzo(a)pyrene (BP), and the results are discussed in terms of their reactivities, mutagenicities, and DNA binding. The results of the computer analysis predicted that C₁₀ would be the preferred site of nucleophilic attack on the epoxide ring, which agrees with experimental findings. Reactions with weak nucleophiles, such as methanol or water, support an S_N1 mechanism involving proton-assisted ring-opening prior to nucleophilic attack at C₁₀. With stronger nucleophiles, ring-opening is trans-stereospecific, and an S_N2 mechanism is implicated. Both isomeric BP DE's have been shown to be highly efficient alkylating agents of DNA, RNA, and purine and pyrimidine homopolymers. The structures of the major bound products following degradation to the nucleotide or nucleoside level involve covalent bonding between the C₁₀ benzylic positions of the BP DE's and the 2-NH₂ group of guanosine. Ring-opening is predominantly trans-stereospecific. These results are consistent with an S_N2 mechanism involving attack by the nucleophilic center on C₁₀ at neutral pH. The theoretical treatment did not consider the fact that the DE's formed metabolically are optically active, as are the nucleic acids and protein reactants that may contribute significantly to reactions between the two. There is some evidence that the enantiomers of the anti and syn BP DE's exhibit differences in mutagenicity; these differences are not predicted from the CNDO/2 calculations. (35 refs)

79-0892 Sustained-Release Endobronchial Carcinogenic Implants. (Eng) Shors, E. C. (Dept. Surgery, UCLA Sch. Medicine, Harbor General Hosp., Campus, Torrance, CA); Fu, P. C.; Matsumura, K.; Cohen, A. H.; Benfield, J. R. *Surg Forum* 29: 205-207; 1978.

A new method for the sustained release of benzo(a)pyrene (BP) at precise endobronchial sites in dogs and hamsters was developed. Silicone rubber implants containing 484-934 μ g BP (hamsters) or 2.93-20.53 mg (dogs) were inserted endo-

bronchially and then removed at intervals during the next 200 days. In both species, BP was released according to a one-compartment exponential function, and the release half-time was 44.4 days. The exponential release rate was 1.56%/day. Preneoplastic changes resulted in the dogs, cancers in the hamsters. (2 refs)

- 79-0893 The Petroleum-inducible Mixed-Function Oxidase of Cunner (*Tautoglabrus adspersus* Walbaum 1792): Some Characteristics Relevant to Hydrocarbon Monitoring.** (Eng) Walton, D. G. (Dept. Zoology, Univ. British Columbia, Vancouver, B.C. V6T 1W5, Canada); Penrose, W. R.; Green, J. M. *J Fish Res Board Can* 35(12): 1547-1552; 1978.

The aryl hydrocarbon hydroxylase (AHH) system of the cunner (*Tautoglabrus adspersus*) was studied to confirm the suitability of this species as a monitoring tool for environmental hydrocarbons. The hepatic benzo(a)pyrene (BP) hydroxylase and 2,5-diphenyloxazole (PPO) hydroxylase activities were twofold greater in males than in prespawning females, but the difference disappeared after spawning. Specific hydroxylase activity and the liver-somatic index decreased about 40% after starvation. Neither uninduced nor induced specific activity correlated with body or liver wt. Exposure to crude oil (0.2-2 mg/liter added to the ambient water) resulted in rapid induction of BP hydroxylation that persisted for 1 wk following exposure. Hydroxylase induction also followed force feeding of 0.1 ml crude oil or feeding of oiled mussel tissue. PPO was a safe substitute for BP in the assay. (20 refs)

- 79-0894 Analysis of Polycyclic Aromatic Hydrocarbons in Raw and Broiled Fishes.** (Jpn) Yamazaki, H. (Faculty Pharmaceutical Sciences, Osaka Univ., 133-1, Yamadakami, Suita-shi, Japan); Minami, J.; Ichikawa, T.; Kondo, M. *J Food Hyg Soc Jpn* 18(4): 368-374; 1977.

Raw, dried, and broiled (over a gas flame, unwrapped or wrapped in aluminum foil) fish were analyzed for the presence of several polycyclic aromatic hydrocarbons (PAH): benzo(a)pyrene (BP), benz(a)anthracene (BA), 1,2,5,6-dibenzanthracene (DBA), and chrysene (CS). None of these PAH were detected in the 17 samples of raw fish analyzed, which included mackerel, sardines, scabbard fish, pomfret, eel, and mackerel pike. However, BP, BA, and CS were detected in salted, dried sardines. In the 33 samples of fish broiled directly over a gas flame, the highest level of BP, BA, and CS found was 0.75, 0.39, and 0.98 $\mu\text{g}/100\text{ g}$. The av level of BP in these samples was 0.13 $\mu\text{g}/100\text{ g}$. None of these samples contained DBA. Only CS was detected in the fish that were wrapped in aluminum foil before being broiled. Only CS was detected in the gas used for broiling. The cholesterol, neutral fats, fatty acids, and carotenoids found in raw fish are assumed to be the source of the PAH detected in the broiled fish. (17 refs)

- 79-0895 Development of Induced Tumors in Rats of Different Ages.** (Bul) Maiski, I. N. (Res. Lab. Experimental Immunobiology, Moscow, USSR); Botev, B.; Airapetian, G. P.; Pokrovska, T. A.; Vatsseva, T.; Markholev, L.; Vatev, I.; Mladenov, I. *Onkologiya* 15(2): 83-87; 1978.

The effect of age on the development of chemically induced tumors was studied in Wistar rats. Animals aged 1, 3, 5, or 9 mo or > 1 yr were inoculated with benzo(a)pyrene (1.8-3.0 mg, sc). Tumor incidence increased with the age of the rats, and it was 62%, 63%, 73%, 86%, and 87%, respectively, for the five age groups. The av latent period of tumor development was 131.5, 136.7, 128.2, 133.63, and 113.8 days, respectively. (7 refs)

- 79-0896 Comparative Tumor Initiating Activity of 10-Methylbenzo(a)pyrene, 7,10-Dimethylbenzo(a)pyrene and Benzo(a)pyrene.** (Eng) Hecht, S. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Hirota, N.; Hoffman, D. *Cancer Lett* 5(3): 179-183; 1978.

The tumor-initiating activities of benzo(a)pyrene (BP), 7,10-dimethyl-BP, and 10-methyl-BP on the skin of Ha (ICR) female outbred Swiss albino mice were compared, to determine the effect of methyl substitution in the angular ring of BP. The compounds (5 or 10 μg) were applied to shaved back skin every other day for 10 doses to a total initiation dose of 50 or 100 μg . Promotion was started 10 days after completion of initiation, and it consisted of topical applications of 12-O-tetradecanoylphorbol-13-acetate (2.5 μg 3x/wk for 20 wk). BP produced 25% and 40% tumor-bearing animals at total doses of 50 and 100 μg , respectively, but no tumors were observed in either of the groups initiated with 7,10-dimethyl-BP. 10-Methyl-BP was slightly but not significantly less active than BP at the higher dose and was as active at the lower dose, producing 20% and 20% tumor-bearing animals, respectively. However, in both cases, the latent periods with 10-methyl-BP were longer than those with BP. The skin tumors were predominantly keratoacanthomas; some papillomas were also seen. These results indicate that methyl substitution at positions 7 and 10 of BP (but not at position 10 alone) was sufficient to inhibit metabolic activation via an angular ring epoxide or diol-epoxide and that alternative pathways are not effective for activation in mouse skin. - 79-0897 Tumorigenicity of Benzo(a)pyrene 4,5-, 7,8-, 9,10-, and 11,12-Oxides in Newborn Mice.** (Eng) Wislocki, P. G. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE, 68105); Kapitulnik, J.; Levin, W.; Conney, A. H.; Yagi, H.; Jerina, D. M. *Cancer Lett* 5(4): 191-197; 1978.

Benzo(a)pyrene (BP), benzo(a)pyrene 4,5-oxide (BP 4,5-ox-

ide), benzo(a)pyrene 7,8-oxide (BP 7,8-oxide), benzo(a)pyrene 9,10-oxide (BP 9,10-oxide), and benzo(a)pyrene 11,12-oxide (BP 11,12-oxide) were tested for carcinogenicity in newborn Swiss Webster mice by ip injection on postnatal days 1, 8, and 15 (200, 400, and 800 nanomoles, respectively). Mice that died after weaning or were sacrificed at 24 wk of age were autopsied. Three of 42 control mice had pulmonary adenomas with an av of 0.08 adenoma/mouse. Twenty-six of 32 mice treated with BP, 38/55 treated with BP 7,8-oxide, 13/67 treated with BP 11,12-oxide, and 4/47 treated with BP 4,5-oxide had pulmonary adenomas with an av of 10.0, 2.1, 0.32 and 0.10 adenoma/mouse, respectively. None of the mice treated with BP 9,10-oxide developed pulmonary adenomas. One mouse treated with BP 7,8-oxide developed an adenocarcinoma at 24 wk of age, and 13% of the mice treated with BP developed malignant lymphomas. The moderate tumorigenic activity of BP 7,8-oxide, together with earlier data on the strong carcinogenicity of benzo(a)pyrene 7,8-dihydrodiol, supports the view that BP 7,8-oxide is a proximate metabolite of BP in the newborn mouse. (23 refs)

- 79-0898 Dose-dependent Preferential Binding of Polycyclic Aromatic Hydrocarbons to Reiterated DNA of Murine Skin Cells in Culture.** (Eng) Shoyab, M. (Meloy Labs., Inc., 6715 Electronic Dr., Springfield, VA, 22151). *Proc Natl Acad Sci USA* 75(12): 5841-5845; 1978.

The distribution of the active metabolites of dimethylbenzo(a)anthracene (DMBA), benzo(a)pyrene (BP), and 3-methylcholanthrene (3-MC) bound to reiterated or unique regions of murine DNA was studied by a DNA-DNA renaturation technique. Murine epidermal cells isolated from the skins of newborn NIH Swiss mice were exposed to ³H-labeled DMBA (0.01-10 μ Ci/ml), BP (1 μ Ci/ml) or 3-MC (1 μ Ci/ml), and the hydrocarbon-labeled DNA was subsequently isolated, mixed with unlabeled normal DNA, and fragmented. Fragments were denatured, reassociated, and fractionated on hydroxyapatite according to their reassociation rates, and the specific activity of single- and double-stranded DNA was determined. At high concentrations of the three carcinogens, the active metabolites appeared to bind to DNA of different repetition frequencies at random. At lower doses, however, they bound preferentially to reiterated DNA sequences in a dose-dependent fashion. Thermal denaturation studies also indicated that ultimate carcinogens bound more to reiterated than single-copy DNA sequences at lower doses. An inverse linear relationship appeared to exist between this enrichment of hydrocarbon adducts in reiterated DNA sequences and the logarithm of the amount of total hydrocarbon bound to DNA. These studies suggest that at very low doses, similar to the constant low levels in the human environment, the intragenomic distribution of polycyclic aromatic hydrocarbons in cellular DNA appears to occur in a nonrandom fashion. sain, M. Z. (Sch. Dentistry, Univ. California, San Francisco, CA, 94132); Tolentino, M.; Belton, J. C.; Lee, S. D.; Bhatnagar, R. S. *J Dent Res* 58(Special A): 108; 1979. (no refs)

- 79-0900 Comparison of the Metabolic Profiles of Benzo(a)pyrene Obtained from Primary Cell Cultures and Subcellular Fractions Derived from Normal and Methylcholanthrene-induced Rat Liver.** (Eng) Schmeltz, I. (Naylor-Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Tosk, J.; Williams, G. M. *Cancer Lett* 5(2): 81-89; 1978.

Benzo(a)pyrene (BP) metabolite profiles produced by hepatocyte primary cell (HPC) cultures and isolated rat liver microsomal (9,000 x g) fractions, both derived from methylcholanthrene (MC)-induced or noninduced (normal) livers of male Fischer rats, were compared. The HPC cultures, both induced and noninduced, actively metabolized BP over a 24-hr period, generating metabolites that were extractable with organic solvents and easily monitored by high-pressure liquid chromatography. In both cases, the BP metabolites (the usual phenols, diols, and quinones) were qualitatively similar to those produced by the microsomal fractions. The HPC system also produced some unidentified metabolites that were found primarily in peak effluents eluting before the 9,10-diol peak. The metabolite profiles of the HPC cultures changed with time. In cells from noninduced livers, the 3- and 9-hydroxy-BP and the 9,10-, 4,5-, and 7,8-diol levels increased over 24 hr, but in cells from induced livers, the diol levels decreased markedly after 8 hr. This suggests that MC induction of the HPC culture enhances both the activation and, to a greater extent, the conjugative-detoxification pathways of BP. Therefore, in cells from induced livers, the formation of water-soluble metabolites is enhanced and levels of ethyl acetate-soluble metabolites are lower. The metabolism of BP in HPC culture is thus similar to the in vivo metabolism of the carcinogen but different from the microsomal metabolism of BP, in which conjugative-detoxification pathways are virtually inoperative, even with enzyme induction. (18 refs)

- 79-0901 Quantitative and Qualitative Changes in the Metabolism of Benzo(a)pyrene in Rat Tissues after Intragastric Administration of TCDD.** (Eng) Uotila, P. (Dept. Physiology, Univ. Turku, SF-20520 Turku 52, Finland); Parkki, M. G.; Aitio, A. *Toxicol Appl Pharmacol* 46(3): 671-683; 1978.

The effect of pretreatment with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD, 20 μ g/kg given intragastrically 1 wk before sacrifice) on the in vitro metabolism of benzo(a)pyrene (BP) by liver, lung, and kidney preparations from Wistar and

Gunn (deficient in glucuronide conjugation) rats was studied. TCDD greatly increased the metabolism of BP to ethyl acetate-soluble metabolites by liver homogenates and microsomes. The increase was greatest in the case of unidentified "near origin" metabolites. 4,5-Dihydrodiol was the major metabolite formed by control liver preparations, whereas the 9,10- and 7,8-dihydrodiols were the major metabolites formed after TCDD treatment. TCDD pretreatment also drastically increased the metabolism of BP to water-soluble metabolites and significantly increased the liver microsomal protein content in Wistar, but not Gunn, rats. The increase in the amounts of phenols and quinones after TCDD treatment was much less pronounced. TCDD greatly increased the metabolism of BP to dihydrodiols, phenols, and unidentified metabolites by kidney and lung microsomes; the increase was greater with kidney microsomes from Gunn rats than with those from Wistar rats. TCDD treatment decreased the protein content of the kidney, and it had no effect on the metabolism of BP to water-soluble metabolites by kidney microsomes. The amount of BP metabolites covalently bound to liver, but not kidney or lung, microsomes was increased by TCDD pretreatment. (35 refs)

79-0902 A Short-Term Test to Detect Organotropic Specificity of Carcinogens. (Eng) Inui, N. (Section Cell Biology and Cytogenetics, Biological Res. Center, Japan Tobacco and Salt Public Corp., Hatano, Kanagawa 257, Japan); Nishi, Y. *Toxicol Lett* 2(5): 277-283; 1978.

A short-term screening method for detecting the organotropism of carcinogens was developed using an in vivo-in vitro combination assay. Induction of transformation, mutation, and chromosome aberrations was determined in cultured embryo cells derived from pregnant Syrian golden hamsters that had been injected ip on the 11th or 12th day of pregnancy with 200 mg/kg benzo(a)pyrene (BP), 200 mg/kg dimethylnitrosamine (DMN), or 100 mg/kg N-nitrosomethylurea (NMU). After BP treatment, morphological transformations were observed in lung and total body cells at rates of 3.70% and 1.45%, respectively. BP also caused chromosome aberrations and a 30.0- and 13.6-fold increase in 8-azaguanine (8AG)-resistant mutation in lung and total body cells, respectively. With DMN, the highest rates of morphological transformation (6.53%) and 8AG-resistant mutation (128/10⁷ cells) were induced in liver cells; chromosome abnormalities were detected in liver and total body cells. NMU caused a marked increase in morphological transformation (4.08% and 4.40%) and 8AG-resistant mutations (134.8/10⁷ and 79.9/10⁷ cells) in brain and total body cells, respectively. These results demonstrate that BP, DMN, and NMU cause chromosomal aberrations, 8AG-resistant mutation, and morphological transformation of cells from specific organs. Since cells cultured from whole embryos gave a positive result, the unknown tissue specificity of a carcinogen need not present an obstacle to an in vivo-in vitro test. (24 refs)

79-0903 Differences in the Repair of DNA Strand Breaks Induced by 9-Hydroxybenzo(a)pyrene and trans-7,8-Dihydro-7,8-dihydroxybenzo(a)pyrene in Cultured Human Fibroblasts. (Eng) Nordenskjold, M. (Dept. Clinical Genetics, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Soderhall, S.; Moldeus, P.; Jernstrom, B. *Biochem Biophys Res Commun* 85(4): 1535-1541; 1978.

The induction of strand breaks in human fibroblast DNA by 9-hydroxybenzo(a)pyrene (9-OH-BP) and trans-7,8-dihydro-7,8-dihydroxybenzo(a)pyrene (BP 7,8-dihydrodiol) and the kinetics of their repair were studied. The fibroblasts were incubated with 30 μ M 9-OH-BP or 10 μ M BP-7,8-dihydrodiol, washed after 30 min, and incubated in fresh medium. Incubation with either agent caused a rapid increase in DNA strand breaks. However, DNA strand breaks induced by 9-OH-BP were repaired within 2 hr of changing the medium, while those induced by BP 7,8-dihydrodiol were present for at least 6 hr. When fibroblasts were incubated with rat liver microsomes and an NADPH-generating system, there was an increased level of strand breaks at 30 min but the repair pattern was generally the same as that in incubations without microsomes. These results correlate well with results from mutagenicity test systems, in which 9-OH-BP is less active than the highly mutagenic BP 7,8-dihydrodiol. The results suggest that binding of activated BP 7,8-dihydrodiol to DNA gives rise to damage that is repaired less efficiently than damage caused by 9-OH-BP. These differences may be responsible for the marked differences in mutagenicity and carcinogenicity between 9-OH-BP and BP 7,8-dihydrodiol. (23 refs)

79-0904 A Human Plasma Component That Binds Benzo(a)pyrene. (Eng) McKenzie, M. (Dept. Biology, North Texas State Univ., Denton, TX, 76203); McLeMORE, T.; Rankin, P.; Martin, R. R.; Wray, N.; Cantrell, E.; Busbee, D. *Cancer* 42(6): 2733-2737; 1978.

Plasma, cultured lymphocytes, and fresh surgically excised lung tissue from smokers and nonsmokers and from smokers with and without primary squamous cell carcinoma of the lung were examined in an attempt to identify a cytoplasmic receptor molecule for benzo(a)pyrene (BP). A component capable of binding BP was measured in plasma from cigarette smokers and nonsmokers. This plasma fraction was found to have a high specificity of binding to BP, it bound benzanthracene competitively with BP, and it was positively correlated ($r = 0.861$, $p < 0.001$) with the capacity of the individual subject's lymphocytes to be induced for AHH activity in culture. The inverse correlation ($r = -0.957$, $p < 0.001$) found between the presence of the plasma component in lung cancer patients and the capacity of their lymphocytes to be induced in culture cannot be explained at this time. A BP-binding fraction was not found in induced or uninduced cultured lymphocytes from smokers or nonsmokers or in homogenates of

lung excisional tissue from smokers with or without primary lung cancer. (29 refs)

- 79-0905 Quantitative Determination of Benzo(a)pyrene in Foodstuffs Using Benzo(a)pyrene[G-³H].** (Jpn) Masuda, Y. (Daiichi Coll. Pharmaceutical Sciences, 93 Tamagawa-cho, Minami-ku, Fukuoka, Japan); Shimamura, K.; Yano, H. *J Food Hyg Soc Jpn* 18(4): 362-367; 1977.

A method for determining nanogram quantities of benzo(a)-pyrene (BP) in foodstuffs using ³H-BP is described. Foodstuff extracts to which ³H-BP was added were separated by column chromatography on Florisil and by thin-layer chromatography on acetylated cellulose. The concentration and radioactivity of BP in the final fraction were determined by fluorescence spectrometry and liquid scintillation counting. The concentration of BP in the analyzed sample was calculated from the amount of BP isolated and the recovery ratio. For a 50-g sample, measurements were accurate at levels >0.5 ppb; a wide variance occurred at levels <0.2 ppb. The method was then applied to various food samples. The av quantity of BP found in Tempura oil, salad oil, wheat flour, and polished (white) rice was 0.6, 0.2, 0.1, and <0.1 ppb, respectively. (17 refs)

- 79-0906 Analysis of Polycyclic Aromatic Hydrocarbon Air Pollutants by High-Pressure Liquid Chromatography.** (Hun) Morlin, Z. (Orszagos Kozegeszsegugyi Intezet, Budapest, Hungary); Kertesz, M.; Kiss, A. M. *Egeszsegtudomany* 22(4): 370-378; 1978.

The quantitative determination of six polycyclic aromatic hydrocarbon environmental pollutants in standard air mixtures and in various environmental samples was made by high-pressure liquid chromatography (HPLC). The air, dust, soot, and snow samples were extracted with benzol and purified by chromatography prior to HPLC. The presence of anthracene, chrysene, pyrene, fluoranthene, benzo(a)pyrene, and 3-methylcholanthrene in various combinations was demonstrated. (14 refs)

- 79-0907 Benzo(a)pyrene Determination in Airborne Soot from Metallurgical Factories.** (Ger) Masek, V. (Na valse 4, 70200 Ostrava-Privaz, Czechoslovakia). *Zentralbl Arbeitsmed Arbeitsschutz Proph* 28(6): 168-170; 1978.

Benzo(a)pyrene (BP) levels in 291 samples of airborne soot and smoke from four types of steel-producing operations were determined. The av airborne BP levels (in micrograms/gram) found near the coking of bituminous coal was 276; near coke ovens producing pitch, 989; near blast furnaces, 9.4; and

near steel production, 11.3. The first two processes expose the worker to dangerous levels of BP. (6 refs)

- 79-0908 Correlation of the Inhibition by Retinoids of Tumor Promoter-induced Mouse Epidermal Ornithine Decarboxylase Activity and of Skin Tumor Promotion.** (Eng) Verma, A. K. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Shapas, B. G.; Rice, H. M.; Boutwell, R. K. *Cancer Res* 39(2, Part 1): 419-425; 1979.

Effects of retinoic acid (RA) and several synthetic retinoids on induction of epidermal ornithine decarboxylase (ODC) activity and formation of skin papillomas promoted with 12-O-tetradecanoylphorbol-13-acetate (TPA) were studied in female Charles River CD-1 mice. Tumors were initiated in all mice by topical application of 0.2 micromole of dimethylbenz(a)anthracene (DMBA) in acetone followed 14 days later by TPA promotion [8 or 17 nanomoles (nmol)] 2x/wk for the duration of the experiment. Various retinoids were administered to mouse skin 1 hr before each TPA treatment. Multiple applications (6-11) of TPA increased ODC activity approx 600-fold, but pretreatment with 1.7 nmol RA inhibited ODC activity 60%-80%, and pretreatment with 1.7 or 17 nmol RA reduced the number of papillomas/mouse by 57% and 75%, respectively. Skin tumor development was not altered by administering RA 24 hr after TPA treatment or at various times before tumor initiation by DMBA. Pretreatment with the trimethylmethoxyphenyl analog of ethyl retinoate, 13-cis-retinoic acid, or the dimethylmethoxyethylcyclopentenyl analog of RA inhibited TPA-induced ODC activity, the number of papilloma-bearing mice, and the number of papillomas/mouse. The trimethylhydroxyphenyl and 13-trifluoromethyltrimethylmethoxyphenyl analogs of ethyl retinoate did not alter these parameters. Although retinoid treatment inhibited ODC activity and the resultant increases in putrescine levels, it did not alter TPA-induced S-adenosyl-L-methionine decarboxylase activity or the accumulation of spermidine and spermine. These findings indicate that RA exerts its prophylactic effect by interfering with promotion and not by inhibiting initiation or inactivating initiated cells. (35 refs)

- 79-0909 Retinoids Induce Sister-Chromatid Exchanges In Human Diploid Fibroblasts.** (Eng) Juhl, H. J. (I. Medizinische Klinik, Universitat Hamburg, Martinistrasse 52, 2000 Hamburg 20, W. Germany); Schurer, C. C.; Bartram, C. R.; Kohl, F. V.; Melderis, H.; von Wichert, P.; Rudiger, H. W. *Mutat Res* 58(2/3): 317-320; 1978.

In view of the contradictory results obtained in carcinogenicity studies with retinoids, experiments were conducted to determine whether these compounds induce sister chromatid

exchanges (SCE) in cultured human diploid fibroblasts. Vitamin A palmitate, retinoic acid, and the retinoic acid analog ethyl all-trans-9- (4-methoxy-2,3,6-trimethylphenyl)-3,7-dimethyl-2,4,6,8-nonatetraenoates (Ro 10-9359) were incubated with fibroblasts (3×10^5 cells) from five healthy individuals in the presence of bromodeoxyuridine (1 or 3 mg/ml) for 72 hr and analyzed for SCE by fluorescence microscopy. All three compounds more than doubled the rate of SCE, causing a max plateau of approx 14 SCE/metaphase. However, the dose of vitamin A palmitate (approx 50 μ g/ml) required to achieve this plateau was 10 times that necessary to cause a similar max by the other two compounds tested. The dose related induction of SCE by a retinoid was apparently unrelated to its previously reported antineoplastic activity. (18 refs)

79-0910 Increased Aryl Hydrocarbon Hydroxylase Activity in Hepatic Microsomes from Streptozotocin-Diabetic Female Rats. (Eng) Reinke, L. A. (Dept. Biomedical Chemistry, Coll. Pharmacy, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE, 68105); Stohs, S. J.; Rosenberg, H. *Xenobiotica* 8(12): 769-778; 1978.

Alterations of hepatic microsomal aryl hydrocarbon hydroxylase (AHH) activity were studied in Sprague-Dawley rats and Swiss Webster mice with streptozotocin (STZ)-induced diabetes (60 and 200 mg/kg iv, respectively). AHH activity was decreased 70% in diabetic male rats but it was increased 75% over control values in diabetic female rats. Insulin treatment of both sexes returned AHH values to control levels. In both male and female diabetic mice AHH activity was 65%-70% higher than that in controls. In female rats, a transient hyperglycemia occurred 4 hr after STZ injection that decreased by 9 hr. At 24 hr after STZ treatment, however, a severe hyperglycemia developed that persisted throughout the study. AHH activity did not increase until 96 hr after injection, and it peaked at 7 days. Cytochrome P-450 levels began to increase at 48 hr to a max at 96 hr. Nicotinamide pretreatment (1,000 mg/kg, ip) of female rats 15 min before STZ injection protected them from the diabetogenic effects of STZ and also prevented the increase in AHH activity. Treatment of control and diabetic female rats (the latter 7 days after STZ) with 3-methylcholanthrene (20 mg/kg/day \times 3, ip) resulted in a larger increase in AHH activity in the former (3.04 and 2.27 units, respectively, vs an untreated control value of 0.30), but similar increases in cytochrome P-448 levels in both. Addition of SKF 525-A, metyrapone, and rotenone to hepatic microsomes of control and diabetic female rats in vitro resulted in differential stimulatory or inhibitory effects on AHH activity. In contrast, α -naphthoflavone (an inhibitor of cytochrome P-448-dependent reactions) produced similar stimulatory responses in microsomes from both rat groups, which suggests that cytochrome P-448 is not involved in the enhanced AHH activity observed in diabetic females. It is concluded that

there is a sex-dependent effect of STZ-induced diabetes on AHH activity in rats. (43 refs)

79-0911 Studies on the Induction of Sister Chromatid Exchange in Human Fibroblasts by Diethylstilbestrol (Meeting Abstract). (Eng) Haensch, F. T. (I. Medizinische Klinik, Univ. Hamburg, Hamburg, W. Germany); Rudiger, H. W. *Clin Genet* 14(5): 291-292; 1978. (4 refs)

79-0912 Cancer Development in Male Reproductive Tract in Rats Given Diethylstilbestrol at Neonatal Age. (Eng) Arai, Y. (Dept. Anatomy, Juntendo Univ. Sch. Medicine, Hongo 2-1-1, Bunkyo-ku, Tokyo 113, Japan); Chen, C. Y.; Nishizuka, Y. *Gann* 69(6): 861-862; 1978.

The effect of daily administration of diethylstilbestrol (DES, 1 μ g sc for first 10 days after birth, 2 μ g for days 10 to 20, and 4 μ g for days 20 to 30) on castrated and intact male Wistar rats was studied. The surface epithelium of the coagulating gland (CG) and ejaculatory duct (ED) showed profound squamous metaplasia in the DES-treated rats. The lumina of the CGs and EDs of the castrated rats were distended by masses of sloughed and cornified cells, and extensive downgrowths and papillary outgrowths of epithelial cells appeared to progress with age. Highly invasive squamous cell carcinomas developed in the CG, ED, and dorsolateral prostate of two castrated rats. Metaplastic changes without downgrowth or outgrowth proliferations of the epithelium were observed in the intact animals. The data indicate a possible correlation between neonatal DES treatment and cancer and suggest the importance of follow-up studies in human males exposed prenatally to DES. (6 refs)

79-0913 Peroxidase-mediated Oxidation, a Possible Pathway for Metabolic Activation of Diethylstilbestrol. (Eng) Metzler, M. (Inst. Toxicology, Univ. Wurzburg, Versbacher Strasse 9, D-8700 Wurzburg, W. Germany); McLachlan, J. A. *Biochem Biophys Res Commun* 85(3): 874-884; 1978.

The oxidation of diethylstilbestrol in the presence of peroxidase preparations from horseradish or mouse uterus, hydrogen peroxide, and either DNA or albumin yielded one or more compounds that interacted with the DNA and albumin. The oxidation reaction appeared to involve the semiquinone and quinone of DES, as demonstrated by nonextractable binding to DNA and bovine serum albumin. Analysis of ether extracts of the complete incubation systems by radio-gas liquid chromatography revealed at least six peaks, three of which were identified as cis- and trans-DES and β -dienestrol

by cochromatography with reference compounds. The peroxidase-mediated binding of DES to DNA and proteins may have relevance for the mechanism by which DES exerts its toxicity. Peroxidase activity is preferentially found in tissues depending on estrogens for growth. Thus, peroxidase-mediated oxidation of DES and binding to DNA can take place in estrogen target organs, which could explain in part the organotropic toxicity of DES. (29 refs)

- 79-0914 The Metabolism of Diethylstilbestrol in the Rhesus Monkey and Chimpanzee.** (Eng) Helton, E. D. (Natl. Center Toxicological Res., Food and Drug Admin. DHEW, Jefferson, AR, 72079); Hill, D. E.; Lipe, G. W.; Szisak, T. J.; King, J. W. *J Environ Pathol Toxicol* 2(2): 521-537; 1978.

To study diethylstilbestrol (DES) metabolism, various doses of radiolabeled DES were administered po or iv to one pregnant and three nonpregnant female rhesus monkeys and to one nonpregnant female chimpanzee. The principal mode of excretion of both tritiated and ^{14}C -DES, regardless of route of administration, was in the urine of both species. The radioactive material in the urine was not extractable with benzene, and the urinary conjugate profiles were similar for all animals. The urine contained no nonpolar radioactivity, and Sephadex LH-20 chromatography [methanol/ethanol (50:50)] resolved the radioactivity into five fractions, A-E. A-D were hydrolyzable with β -glucuronidase, and the principal aglycones were identified by gas chromatography/mass spectrometry (GD/MS) as cis-trans DES and dienestrol. The fecal excretory products were extracted with dimethoxymethane/methanol (50:50), and the radioactivity was partitioned between benzene and water. The polar radioactivity was resolved by LH-20 into chromatographic fractions similar to those of the urinary conjugates. However, these fecal conjugates were less sensitive to β -glucuronidase hydrolysis. The primary nonpolar fecal radioactivity was chromatographically similar to DES in both species, and in the rhesus monkey the principal products identified were cis-trans DES and dienestrol. (28 refs)

- 79-0915 Study on the Mutagenicity of Conjugated Estrogens in Human, Animal and Bacterial Systems.** (Eng) Sirianni, S. R. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Hale, P.; Brown, M.; Huang, C. C.; Paigen, B.; Ambrus, J. L. *J Med Clin Exp Theor* 9(5): 423-432; 1978.

The direct mutagenic effect of conjugated estrogens (Premarin) was studied in bacterial and mammalian systems, includ-

ing normal and neoplastic human cell lines. Two strains of *Salmonella typhimurium* (TA100 and TA98), 2 normal human lymphoid cell lines, 3 lymphoid cell lines from patients with Burkitt's lymphoma (B-35 M, HRIK, and Raji), and 1 Chinese hamster cell line (V-79) were exposed continuously to estrogens at 50 $\mu\text{g}/\text{ml}$. Following colcemid treatment, metaphases were studied for chromosome lesions. Diffusion chamber cultures were established and implanted into the abdominal cavity of mice. Three days later, the animals were injected ip with 25-400 $\mu\text{g}/\text{g}$ of estrogens. Cell viability, number, and cytogenic characteristics were determined following colchicine injection into the chambers. There were no significant increases in mutation rate or chromosome aberrations after exposure of the test material to the conjugated estrogens. (37 refs)

- 79-0916 Primary and Transplantable Adenocarcinomas of the A x C Rat Ventral Prostate Gland: Morphologic Characterization and Examination of C_{19} -Steroid Metabolism by Early-Passage Tumors.** (Eng) Shain, S. A. (Southwest Foundation Res. and Education, P.O. Box 28147, San Antonio, TX, 78284); McCullough, B.; Nitchuk, W. M. *J Natl Cancer Inst* 62(2): 313-322; 1979.

Spontaneous adenocarcinomas of the ventral prostate glands in 23/33 aged (30-46 mo old) virgin male A x C rats are described. Eleven of the 23 tumor-bearers had received a single im injection of 15 mg testosterone-p-hexoxyphenyl propionate (Andradurin). Multiple acini and focal atypical hyperplasia were common morphologic features of the adenocarcinomas, which were bilateral in six rats. Atypical hyperplasia of ventral prostate acinar epithelium was found in atrophic as well as neoplastic epithelium. It consisted of thickened epithelium in which various numbers of cells had a swollen, foamy, PAS-positive cytoplasm and condensed, eccentric nuclei. Andradurin treatment caused the development of columnar epithelium in many ventral prostate acini, increased the frequency of adenocarcinoma, and amplified the anaplastic character of the neoplastic cells. Although no evidence of metastasis was seen, prostate adenocarcinomas obtained from 2/4 Andradurin-treated rats produced transplantable tumors when injected sc into syngeneic recipients. The histologic features of these tumors were comparable to the primary lesions from which they were derived. The transplantable adenocarcinomas metabolized testosterone predominantly to 17-ketosteroids, which accounted for 61% to 73% of the elaborated metabolites. The principal metabolite, 4-androstenedione, represented 48%-61% of the total metabolic products. Concomitantly, 5 α -reduced 17 β -hydroxysteroid production decreased. Most acid phosphatase activity of the transplantable adenocarcinoma was tartrate-inhibitable. These studies indicate that the aged male A x C rat offers an opportunity to study the pathogenesis of prostate neoplasia without the application of carcinogens. (29 refs)

79-0917 In Vitro Effects of Hormonal Stimuli upon Tyrosinase and Peroxidase Activities in Murine Melanomas. (Eng) Abramowitz, J. (Dept. Biology, Wayne State Univ., Detroit, MI, 48202); Chavin, W. *Biochem Biophys Res Commun* 85(3): 1067-1073; 1978.

Changes in tyrosinase and peroxidase activities in murine melanomas in response to ACTH and corticosterone (CS) were compared in vitro. B-16, Cloudman S-91, and Harding-Passey (HP) melanoma dices were treated with ACTH (100 mIU/ml) and/or CS hemisuccinate (50 µg/ml). The incubates were terminated at seven intervals (5-240 min), and the enzyme activities were determined. ACTH and CS altered tyrosinase activity in all three melanomas but not in any consistent pattern, in some cases stimulating activity, in other cases depressing it, depending on the time interval studied. ACTH + CS produced an early peak in tyrosinase activity in all three tumors; it was observed at 15 min in the B-16 and S-91 melanomas and at 30 min in the HP melanoma. Activity decreased subsequent to this peak; a second higher peak occurred at 240 min in the S-91 and HP melanomas. There were no changes in peroxidase activity following hormone treatment. Tyrosinase activity, but not peroxidase activity, was correlated with the amount of melanin in the melanomas. It is concluded that tyrosinase is the enzyme of physiological importance in the regulation of melanin pigmentation. (35 refs)

79-0918 On the Biological Activity of Estrone In Vivo. (Eng) Thijssen, J. H. (Dept. Endocrinology, Univ. Hosp., Catharijnesingel 101, Utrecht, Netherlands); Wiegerinck, M. A.; Mulder, G.; Poortman, J. *In: Front Horm Res* 5: 220-229; 1978.

Estrogen levels in the myometrium and endometrium of six postmenopausal women were measured and compared with levels in peripheral blood after a 12-hr infusion of 4 µCi/hr ³H-estrone (total dose, approx 0.3 µg estrone). Infusion and sampling were done in conjunction with a hysterectomy performed on all women for nononcological reasons. Protein-bound radioactive estrogens in tissue were measured by a combination of thin-layer chromatography, gas-liquid chromatography, and liquid scintillation counting. In three patients, the ³H-estrone/³H-estradiol ratio was much greater in the tissues (bound to protein in cytosol) than in the plasma. This increase was not seen in the fourth patient, the only one who displayed premenopausal estrogen concentrations in blood, indicating a production of estradiol in addition to the conversion of estrone to estradiol. In the fifth patient, in whom the infusion was stopped 2 hr before hysterectomy (because of mechanical problems), the increase in estradiol concentration of the receptor-bound radioactivity was even more marked. In the sixth patient, the level of receptor-bound estrogens in the nucleus and that of nonreceptor-bound estrogens in the cytosol and nuclei could also be obtained. The

observed high ratio in the nuclear-bound fractions confirmed the previously documented results. Local factors favoring the formation of estradiol from estrone in the cells of the uterus may explain the differential in estrone/estradiol ratios between peripheral blood and uterine tissue. The relation between certain malignancies and an increased estrone production is probably due to an increased biological activity of estrogens rather than to specific separate effects of estrone. 79-0919 Spontaneous Rupture of a Liver Adenoma Following Long-Term Use of Oral Contraceptives. (Ger) Pollak, H. (Chirurgische Klinik, Stadt. Krankenhaus, D-7730 Villingen-Schwenningen, W. Germany). *Munch Med Wochenschr* 121(3): 93-94; 1979.

Hepatocellular adenoma of the liver with hepatic peliosis was found in a 34-yr-old woman who had been using oral contraceptives (0.5 mg Norgestrel and 0.05 mg ethinyl estradiol) for the last 10 yr without interruption. The adenoma ruptured spontaneously. (17 refs)

79-0920 Mesonephric Tumor of the Cervix Uteri in Infancy. (Ger) Scharli, A. F. (Kinderchirurgische Abteilung, Kinderspital, CH-6004 Luzern, Switzerland); Gnös, P.; Laissue, J. *Z Kinderchir* 25(2): 164-169; 1978.

Two cases of mesonephric tumor of the uterine cervix in young girls (2 and 3 yr old) are presented. The mother of the first patient had been treated at the end of the first trimester for threatened miscarriage with six injections of estrogen and six of progesterone. Colposcopy is valuable for determining the cause of vaginal bleeding in children. Any history of hormonal treatment of the mother during pregnancy should be recorded. (11 refs)

79-0921 Cancer of the Prostate and Breast. (Por) de A. Rocha, L. C. (Santa Casa da Misericórdia de Curitiba, Curitiba, PR, Brazil); Rocha, J. A. *J Bras Urol* 4(3): 218-220; 1978.

Prostatic adenocarcinoma was diagnosed in a 84-yr-old man. He received hormone treatment with ethylstilbestrol diphosphate (1.5 g/day, total dose 18 g) and estradiol valerianate (Primogyna Depot im, dose not given). He developed first bilateral gynecomasty and eventually ductal carcinoma of the breast 2 yr after the diagnosis of the prostatic adenocarcinoma. (7 refs)

79-0922 Influence of Low-dose Mutagen Exposure on the Association of Human Acrocentric Chromosomes (Meeting Abstract). (Eng) Hens, L. (Inst. Morphology, Lab. Anthropogenetics, Free Univ. PHYSICAL CARCINOGENESIS

79-0924 DNA Repair In Xeroderma Pigmentosum Cells Treated with Combinations of Ultraviolet Radiation and N-Acetoxy-2-acetylaminofluorene. (Eng) Ahmed, F. E. (Dept. Biology, Brookhaven Natl. Lab., Upton, NY, 11973); Setlow, R. B. *Cancer Res* 39(2, Part 1): 471-479; 1979.

Excision repair was examined in three normal human fibroblast lines and a xeroderma pigmentosum (XP) variant (excision repair-proficient) and in XP types C, D, and E (excision repair-deficient) after they were treated with UV irradiation (254 nm) and/or N-acetoxy-2-acetylaminofluorene (AAAF). Three quantitative techniques were used: unscheduled DNA synthesis measured radioautographically, the photolysis of 5-bromo-2'-deoxyuridine (BrdUrd) incorporated into parental DNA during repair, and the loss of sites (pyrimidine dimers) sensitive to a UV endonuclease. Saturation doses of 20 joules UV/m² and 30 mM AAAF were used for combined treatments. The three techniques gave similar results. In repair-proficient cells, total repair was additive. In repair-deficient XP cells total repair was much less than additive and AAAF inhibited the excision of pyrimidine dimers. It is concluded that pathways for the repair of UV- and AAAF-induced lesions are not identical in the repair-proficient cells and that in repair-deficient cells there is an inhibitory effect exerted by major or minor products of each agent on the repair enzyme(s) of the other. 79-0933 Pattern of Ultra-violet-Light-induced Repair in Metaphase and Interphase Chromosomes. (Eng) Johnson, R. T. (Dept. Zoology, Univ. Cambridge, Downing St., Cambridge CB2 3EJ, England); Sperling, K. *Int J Radiat Biol* 34(6): 575-582; 1978.

The interchromosomal distribution of unscheduled DNA synthesis during the first hour of repair and its intrachromosomal location after UV irradiation (60 joules/m²) of cells arrested in metaphase were examined in heteroploid

HeLa cells and in three human diploid fibroblast cultures. The fibroblasts were obtained from a patient with Fanconi's anemia, a parent of a patient with xeroderma pigmentosum (ie, a xeroderma pigmentosum heterozygote), and a control with apparently normal repair capacity. The interphase chromosomes were visualized by cell fusion and the induction of premature chromosome condensation (PCC). The amount of unscheduled DNA synthesis among the chromosomes of each cell line was similar and was not affected by hydroxyurea (HU: 10^{-2} M). The intrachromosomal distribution of repair was nonrandom for each cell line, with a clear enrichment of label at the centromere and telomeres. The centromere-telomere (CT) pattern of repair was also observed in interphase chromosomes obtained from the G₂ nucleus. These results show that 50% of metaphase chromosome repair and 30% of G₂ chromosome repair is associated with 30% and 20% of the chromosome lengths, respectively. The data show that the amount of initial repair is proportional to chromosome length and therefore to DNA content. They also show that the CT pattern is not influenced by heteroploidy nor by the genetic disease Fanconi's anemia. (22 refs)

- 79-0934 Different Repairability of the Chromosomal and Cytoplasmic Deoxyribonucleic Acid in *Escherichia coli* Damaged by γ and Ultraviolet Irradiation.** (Eng) Petranovic, D. (Institute "Ruder Boskovic", P. O. Box 1016, 41001 Zagreb, Croatia, Yugoslavia); Petranovic, M.; Noznic, R.; Trgovcevic, Z. *Radiat Res* 76(3): 587-595; 1978.

The relative efficiencies with which chromosomal and extra-chromosomal DNA's are repaired in irradiated bacteria were determined by exposing repair-proficient *Escherichia coli* C600 cells lysogenic for, or infected with, the thermoinducible phage λ cI857 to γ or UV radiation, then testing them for colony- and plaque-forming ability. The bacteria were at most 5.3-fold more sensitive to γ rays and 1.5-fold more sensitive to UV light than phage that was irradiated and repaired in the cytoplasm or irradiated in the bacterial chromosome and repaired in the cytoplasm after heat induction. Since the bacterial DNA is about 80 times larger than the phage DNA, the difference in radiosensitivity between the bacterial cells and intracellularly irradiated phage may reflect a difference in repair of the chromosomal and cytoplasmic DNA. This view was supported by the observation that the absence of repair in the system *E. coli* AB2480 *uvrA recA*- λ cI857 *ind red* gave the expected ratio of 80:1 for the UV sensitivity of cells and that of intracellular phage. - 79-0937 Ultraviolet Light Induces Epidermal Ornithine Decarboxylase Activity.** (Eng) Lowe, N. (Section Dermatology, Univ. Wisconsin, Madison, WI); Verma, A. K.; Boutwell, R. K. *J Invest Dermatol* 71(6): 417-418; 1978.

Changes in epidermal ornithine decarboxylase (ODC) activity after exposure to UV light (0.90 J/cm^2) were studied in female HKH/Hr hairless mice. ODC activity increased significantly 2 hr after UV exposure. A max eighty fold increase was observed 24 hr after UV exposure, the level of activity decreasing again at 48 hr. Epidermal DNA synthesis decreased significantly at 6 and 24 hr after UV exposure. It was significantly elevated 48 hr after exposure. The results indicate that polyamine biosynthetic enzyme activity precedes the delayed increase in epidermal DNA synthesis following UV exposure. (14 refs)

- 79-0938 Ultraviolet-Light Induced Transformation of Human Cells (Meeting Abstract).** (Eng) Sutherland, B. (Dept. Biology, Brookhaven Natl. Lab., Upton, NY, 11973); Oliver, R.; Gih, A.; Cimino, J. S. *Biophys J* 25(2, part 2): 87a; 1979. (no refs)

- 79-0939 8-Methoxypsoralen Induced Alterations of Mammalian Cells.** (Eng) Evans, D. L. (Dept. Microbiology and Immunology, Bowman Gray Sch. Medicine, Wake Forest Univ., Winston-Salem, NC, 27103); Morrow, K. J. *J Invest Dermatol* 72(1): 35-41; 1979.

In vitro and in vivo assays demonstrate that 8-methoxypsoralen, in the presence of UV light (8-MOP-UV), causes morphologic changes in cell growth characteristics and stimulates endogenous murine leukemia virus (MuLV) production in certain mammalian cells. Transformation for certain growth characteristics occurred in high percentages of 8-MOP-UV-treated primary mouse, rat, and hamster embryo cultures and in continuous cell lines (BHK₂₁/Cl₁₃, NIH/3T3, and BALB/c 3T3). Morphological alterations were observed at both macroscopic (focus formation) and microscopic (random growth patterns, multilayering, etc.) levels of examination. Treated cells that demonstrated altered phenotypes were tested for growth in soft agarose. Those cultures with altered morphology and whose cells grew in soft agarose were, in addition, tested for MuLV production by the XC cytopathogenicity test. 8-MOP-UV-transformed mouse, rat,

and hamster (except BHK₂₁/Cl₁₃) cells produced positive XC results. Fluorescent antibody tests of cells that produced giant cell cytopathogenicity were positive. Cytoplasmic fluorescence was observed when these cells were tested with antisera to oncornavirus group-specific (gs-3) antigen. Control untreated cells were negative in all experiments. Hamster embryo fibroblasts transformed with 8-MOP-UV acquired apparent unlimited in vitro growth characteristics (>150 population density levels); they exhibited mixoploidy; small numbers of these cells caused spindle cell sarcomas in hamster cheek pouches and produced tumors in newborn hamsters; and their generation times (mean, 22.5 hr) were characteristic of transformed cells. Expression of altered growth characteristics by BHK₂₁/Cl₁₃ cells may be related to selection for cytotoxicity-resistant cells rather than being caused by 8-MOP-UV-induced transformation. (39 refs)

79-0940 Relative Contribution of Unrepaired Single Strand and Double Strand DNA Breaks to Biological Damage (Meeting Abstract). (Eng) Cole, A. (Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Texas Medical Center, Houston, TX, 77030); Meyn, R. E.; Chen, R. *Biophys J* 25(2, part 2): 155a; 1979. (no refs)

79-0942 Protease Inhibitors Suppress Radiation-induced Malignant Transformation In Vitro. (Eng) Kennedy, A. R. (Lab. Radiobiology, Dept. Physiology, Harvard Univ., Sch. Public Health, Boston, MA, 02115); Little, J. B. *Nature* 276(5690): 825-826; 1978.

The effects of antipain (AP) and leupeptin (LP) on radiation-induced and two-stage transformation in vitro were investigated in a C3H mouse embryo-derived cell line (10T 1/2 clone 8) or in a BALB/3T3 line (A31-11). In 10 1/2 cells, AP (50 µg/ml) suppressed x-ray-induced transformation, (600 rads) and completely abolished radiation transformation (400 rads) enhanced by 12-O-tetradecanoyl-phorbol-13-acetate (TPA, 0.1 µg/ml). LP (50 µg/ml) suppressed radiation transformation with and without TPA promotion, but it did not seem as effective as AP. In these experiments, AP and LP were present for the entire postirradiation expression period of 6 wk. AP at 1 mM reduced transformation from 2.0×10^{-3} to $< 3.2 \times 10^{-4}$ when present for 5 days and to 5.5×10^{-4} when present for only 1 day following 600 rads. AP also completely suppressed the transformation induced in A31-11 cells by 100 or 400 rads of x-rays plus TPA. The results offer

in vitro confirmation for the suppressive effect of protease inhibitors on carcinogenesis in vivo. (23 refs)

79-0943 Induction of Gamma-Endonuclease Sensitive Sites by Gamma-Radiation in Mammalian Cells and Their Cellular Repair are not Affected by the Presence of Thiol Compounds During Irradiation (Meeting Abstract). (Eng) van der Schans, G. P. (Medical Biological Lab. TNO, 2280 AA Rijswijk Z.H., Netherlands); Centen, H. B. *Int J Radiat Biol* 34(6): 550; 1978. (1 ref)

79-0944 The Ultrastructure of Mouse Testicular Interstitial Tissue Containing Plutonium-239 and Its Significance in Explaining the Observed Distribution of Plutonium in the Testis. (Eng) Ash, P. (MRC Radiobiology Unit, Harwell, Didcot, Oxon, England); Parker, T. *Int J Radiat Biol* 34(6): 523-536; 1978.

The distribution of plutonium-239 (²³⁹Pu) in the testis of CBA mice at various times after injection was studied by autoradiography of Araldite-embedded sections. The mice were injected in ²³⁹Pu (10 µCi/kg iv, as Pu citrate) when 12 wk old and killed 6 hr, 1 wk, 1 mo, and 3 mo later. At 6 hr, the testis contained 0.06% of the injected ²³⁹Pu; at 1-3 mo, this amount was reduced to 0.02%. At 6 hr, 38% of the ²³⁹Pu deposited in the testis was located within the seminiferous tubules, but this amount was reduced to 14% by 3 mo. At 1 wk to 3 mo, 78%-86% of the ²³⁹Pu was located within the interstitial tissue. Early in this period, ²³⁹Pu was deposited diffusely in the interstitial tissue, but by 3 mo, 47% was concentrated in the macrophages. This was a real change in distribution, since the amount of ²³⁹Pu in the testis remained constant from 1 wk to 3 mo. Electron microscopy indicated that the accumulation of ²³⁹Pu in the macrophages may occur in two ways: (1) phagocytosis of dead cells containing ²³⁹Pu; and (2) ²³⁹Pu may follow the transfer of waste products of hormone synthesis from Leydig cells into macrophages. If the second pathway proves correct, there would be a buildup of ²³⁹Pu in macrophages following injection of even small amounts, which could result in the increased irradiation of spermatogonial stem cells. 79-0945 Neutron Carcinogenicity in Man (Meeting Abstract). (Eng) Bond, V. P. (Brookhaven Natl. Lab., Upton, NY). *Health Phys* 35(6): 882-883; 1978. (3 refs)

79-0946 Enhancing and Inhibiting Effects of Histone Fractions on Film Sarcoma. (Eng) Lavelle, S. M. (Dept. Experimental Medicine, Univ. Coll., Galway, Ireland); MacIomhair, M. *Ir J Med Sci* 147(4): 145-150; 1978.

The effects of crude and fractionated calf thymus histone on film-induced sarcoma were examined in BALB mice. Crude histone and five fractions (2 lysine-rich, 2 slightly lysine rich, and 1 arginine-rich) were incorporated in Millipore filters that were afterward impregnated with gelatin. The filters were implanted into 20 mice for each test substance, and the animals were observed for 100 wk. The tumor yield in the model was low (2/20), but it was reproducible among three groups of controls. In the groups receiving the arginine-rich fraction and the two lysine-rich fractions, tumor yield was double that of controls (4/20 vs 2/20). The crude histone fraction and one of the slightly lysine-rich fractions (f2a) were mildly inhibitory to sarcoma induction. The other slightly lysine-rich fraction (f2b) was significantly inhibitory. Other studies on f2b fractions in several systems have suggested an effect on differentiation rather than on growth. Whether these findings have any relation to the occasional spontaneous regression of human tumors has yet to be determined. (42 refs)

- 79-0947 Thyroid Carcinoma Induced by Irradiation for Hodgkin's Disease. Report of a Case.** (Eng) Weshler, Z. (Dept. Oncology, Sharett Inst. Oncology, Hadasah Univ. Hosp., Jerusalem, Israel); Krasnokuki, D.; Peshin, Y.; Biran, S. *Acta Radiol [Oncol] (Stockh)* 17(5): 383-386; 1978.

A bilateral multifocal, mixed (papillar/follicular) adenocarcinoma of the thyroid was found in a 22-yr-old patient 16 yr after a total of 20 Gray units of radiation was applied to both sides of the neck, supraclavicular regions, and axillae for lymphocytic type Hodgkin's disease. Intermediate stages between adenoma and papillary and follicular adenocarcinoma were present. (17 refs)

- 79-0948 Breast Cancer Incidence among Atomic Bomb Survivors: Implications for Radiobiologic Risk at Low Doses.** (Eng) Land, C. E. (Environmental Epidemiology Branch, Div. Cancer Cause and Prevention, NCI, NIH, Public Health Service, U.S. Dept. Health, Education, and Welfare, Bethesda, MD, 20014); McGregor, D. H. *J Natl Cancer Inst* 62(1): 17-21; 1979.

The results of dose-response analyses of 1950-1969 breast cancer incidence data for Japanese survivors of the atomic bomb blasts in Hiroshima and Nagasaki are presented. In seeking evidence of a dose effect, a summary contingency analysis was used with a single linear contrast for increasing linear dose with av breast cancer dose. The procedure was adjusted for possible confounding between dose and age at time of blast or city of exposure and concentrated statistical power on the hypothesis that incidence increased linearly with increasing dose. It was found that the inference for a radiation effect did not depend solely on interpolation between values

of 0 and high doses. In a second analysis, a theoretical form suggested by radiobiologic principles was used to investigate the extent to which linear interpolation may overestimate or underestimate breast cancer risk at low doses. The analysis provided direct evidence of a radiation carcinogenesis effect to the breast at doses < 40 rads to breast tissue. The paucity of incidence data required simplification of the original linear form for the dose response, but the risk estimate obtained with the use of the simplified form was not greater than estimates obtained with models that fit the data more closely. (8 refs)

- 79-0949 Adenocarcinoma of the Gallbladder in Guinea Pigs.** (Eng) Hoch-Ligeti, C. (Registry Experimental Cancers, Div. Cancer Cause and Prevention, NCI, NIH, Public Health Service, U.S. Dept. Health, Education and Welfare, Bethesda, MD, 20014); Congdon, C. C.; Deringer, M. K.; Stewart, H. L. *J Natl Cancer Inst* 62(2): 381-386; 1979.

Adenocarcinoma of the gallbladder was studied in two inbred strains (2 and 13) and one noninbred stock of guinea pigs exposed to whole-body γ - or x-irradiation (8.8-0.11 R, 8 hr/day, from young adulthood to death or until a predetermined integral exposure had been given, or single doses of 310, 360, or 420 R) or left untreated for their lifespans. Tumors developed in 17/68 untreated and 26/83 irradiated animals of strains 2 and 13. Although the effect of irradiation was not dose-dependent, irradiation of inbred males increased the occurrence of gallbladder carcinoma from 19% to 30% and the number with metastases from 14% to 86%, suggesting an indirect systemic effect of irradiation. Inbred females did not show this increase. Significantly fewer (9/98) noninbred than inbred animals of either sex developed tumors after irradiation, and no gallbladder carcinomas were found in nine untreated noninbred guinea pigs. The tumors were mostly well-differentiated and located in the fundus or neck of the gallbladder. The intrahepatic bile ducts were never involved in the carcinomatous process, but they were often distended and obstructed. Direct invasion to the liver was the most common route for metastasis, as well as through lymphatic and blood vessels to lymph nodes, mesenteries, omenta, abdominal wall, liver, lungs, bones, and spleen. This is the first report of the occurrence of spontaneous gallbladder adenocarcinoma in guinea pigs. (10 refs)

VIRAL CARCINOGENESIS

- 79-0950 Identification of Avian Leukemia Virus by the RIP Test.** (Rus) Zaretskaia, L. I. (All-Union Veterinary Res. Inst. Poultry Farming, Moscow, USSR); Popova, L. S.; Zelenskii, V. P. *Veterinariia* (10): 98-99; 1978.

The restricted interference phenomenon (RIP) test was used to identify avian leukemia virus (ALV). The test is based upon the strict specificity of the interference phenomenon between ALV and Rous sarcoma virus (RSV). Liver and spleen specimens obtained from chickens with a provisional diagnosis of lymphoid leukemia were analyzed by complement fixation for the presence of group-specific (GS) antigen. Cultures that contained GS antigen at a titer of 1:16-1:64 were added to primary cultures of chick embryo fibroblasts (CEF); after two passages, these cultures were infected with RSV. The CEF culture was considered to be contaminated with ALV if it was > 10 times more resistant to infection with RSV than control CEF cultures. Thirty-three variants of leukemia-sarcoma viruses were isolated among the 87 sample cultures, 12 of which were identified as ALV. Serologically, they comprised 5 A-type, 2 B-type, 2 C-type, 1 D-type, and 2 AB-type strains. (no refs)

- 79-0951 Specific RNA Sequences and Gene Products of MC29 Avian Acute Leukemia Virus.** (Eng) Mellon, P. (Dept. Molecular Biology and Virus Lab., Univ. California, Berkeley, CA, 94720); Pawson, A.; Bister, K.; Martin, G. S.; Duesberg, P. H. *Proc Natl Acad Sci USA* 75(12): 5874-5878; 1978.

The *onc* gene of the defective avian acute leukemia RNA virus MC29 was defined biochemically and compared to the *src* gene of Rous sarcoma virus (RSV). Specifically, MC29-specific sequences on the viral genome (a 28S RNA) were identified and located, and the proteins encoded by these sequences were investigated. Using ring-necked pheasant virus as a helper, MC29-specific sequences and sequences hybridized by DNA complementary to other avian tumor virus RNA's [group-specific (GS) cDNA] were defined in terms of their RNase T₁-resistant oligonucleotides and located on a map of all large T₁ oligonucleotides of viral RNA. Sixty percent of sequences were hybridized by GS cDNA, and 40% were hybridized only by MC29-specific cDNA. Oligonucleotides of GS sequences mapped between 0.0 and 0.4 and between 0.7 and 1 map unit from the 3'-poly(A) end, but oligonucleotides of MC29-specific sequences mapped between 0.4 and 0.7 map unit. Cell-free translation of MC29 RNA yielded three proteins with approx mol wts of 120,000 (P120mc), 56,000 (P56mc), and 37,000 (P37mc). P120mc, which is translated only from full-length 28S RNA, contained both MC29-specific peptides and serological determi-

nants and peptides of the conserved, internal GS antigens of avian tumor viruses. MC29 RNA contained sequences related to the GS *gag* gene, found near the 5' end, that were followed by M29-specific sequences. It is concluded that P120mc is translated from the 5' 60% of the RNA and that it includes a segment translated from the specific sequences. The transforming *onc* gene of MC29 may consist of the specific and some GS RNA sequences, and P120mc, which is also found in transformed cells, may be the *onc* gene product. (36 refs)

- 79-0952 Replication Defective, Transforming Virus of Strain R Avian Erythroblastosis Virus.** (Eng) Owada, M. (Res. Inst. Microbial Diseases, Osaka Univ., Yamada-kami, Suita, Osaka-fu 565, Japan); Kamahora, T.; Yoshida, M.; Toyoshima, K. *Gann* 69(6): 857-858; 1978.

Nonproducer (NP) cells induced by transformation of chick embryo fibroblasts (CEF) with avian erythroblastosis virus (AEV) strain R were studied. The transformed cells were highly refractile and had a slender fusiform morphology. Virus production was negative as determined by focus and reverse transcriptase assays, but transforming virus was rescued after superinfection of the NP cells with Rous-associated virus 1 (RAV-1). AEV thus rescued showed subgroup A host range, whereas the infecting AEV-R showed subgroup B host range. The morphologies induced by AEV-R and the rescued AEV-R were identical. Infectious center assay of rescued AEV and AEV-R showed reduction of focus formation to about 1/20 to 1/40 of normal. Polyacrylamide gel electrophoresis of the RNA from the rescued virus showed two major peaks, one corresponding to RAV-1 RNA and one specific for AEV. (11 refs)

- 79-0953 Selection of Methionine tRNAs by Avian Oncocornaviruses.** (Eng) Piper, P. W. (Dept. Molecular Virology, Imperial Cancer Res. Fund Labs., Lincoln's Inn Fields, London WC2A 3PX, England); Elder, K. T. *Nucleic Acids Res* 5(12): 4761-4779; 1978.

In view of the finding that the free 4S RNA of avian RNA tumor viruses is greatly enriched in one of the four methionine transfer RNA's of the host cells, tRNA-Met, the difference in the relative proportions of tRNA-Met isoacceptors in host cell, viral-free, and viral 70S-associated tRNA pools was investigated. It was assumed that the viral tRNA-Met forms are identical to the corresponding tRNA's of mouse and chick cells. Specifically, three hypotheses were analyzed: (1) the three tRNA-Met isoacceptors tRNA-Met,

tRNA-Met₃, and tRNA-Met₄ (forms 2-4) could be functionally disparate and insert methionine at different AUG codons in messenger RNA; (2) the three forms might not represent three distinct tRNA's but various conformations or modification states, separable by column chromatography, of a single nucleotide sequence; (3) form 4 could be preferentially acquired by oncornaviruses as the result of an unequal distribution of isoacceptor tRNA's within different compartments of the host cell. There was no evidence of a role for different tRNA-Met isoacceptors in the tRNA modulation of protein synthesis. Structural studies of forms 3 and 4 of mouse myeloma cells showed that these two tRNA's differ in primary structure and are not interconvertible by modification. The third hypothesis was tested by analyzing the tRNA-Met isoacceptor content of crude chick fibroblast cell fractions isolated by differential centrifugation. The results suggest that tRNA-Met species are partitioned into different cellular compartments; ie, cellular compartmentalization of tRNA's might be the major factor preventing the incorporation of significant amounts of forms 1-3 into viral-free 4S RNA. Avian myeloblastosis virus reverse transcriptase was shown to bind specifically form 4 and tRNA-Trp in whole-cell tRNA. Therefore, the free form 4 in the virion particle may exist substantially bound to virion-associated transcriptase. Although form 4 has no primer role in DNA synthesis, its association with transcriptase is possibly not fortuitous. (29 refs)

- 79-0954 Analysis of Integrated Avian RNA Tumor Virus DNA in Transformed Chicken, Duck, and Quail Fibroblasts.** (Eng) Sabran, J. L. (Dept. Microbiology, Univ. Pennsylvania, Philadelphia, PA, 19174); Hsu, T. W.; Yeater, C.; Kaji, A.; Mason, W. S.; Taylor, J. M. *J Virol* 29(1): 170-178; 1979.

The state of integration of avian sarcoma virus DNA in the genomes of transformed chicken, duck, and quail fibroblasts was deduced by restriction enzyme digestion of total cell DNA, gel electrophoresis, and subsequent analysis by the procedure of Southern using a ³²P-labeled complementary DNA probe made with viral RNA as a template. The cells used were either mass-infected cultures or clones of infected cells selected by their ability to form colonies in agar. For both mass-infected cultures and clones of cells of all three species, integration occurred at a specific site on the viral genome but appeared to occur at many sites on the cell genome. At least some of the integrated viral DNA existed as intact nonpermuted species flanked by direct terminal repeats of least 0.134 megadalton (217 base pairs). For each of 12 transformed quail clones studied, it was possible to detect, after digestion with *Kpn*I, unique junctions between viral and cellular DNA. That is, at the level of analysis used in this study, the integration site on the cell genome for each clone was different. However, within each of the 17 chicken and 9 duck clones of transformed cells, a heterogeneity presumably occurred during the outgrowth of the cell clone popula-

tion, in that identifiable cell-virus junction fragments could not be detected readily. (24 refs)

- 79-0955 Isolation of a Sarcoma Virus from a Spontaneous Chicken Tumor.** (Eng) Itohara, S. (Veterinary Pathology, Faculty Agriculture, Yamaguchi Univ., Yoshida, Yamaguchi 753, Japan); Hirata, K.; Inoue, M.; Hatsuoka, M.; Sato, A. *Gann* 69(6): 825-830; 1978.

A sarcoma virus isolated from a spontaneous tumor of a White Leghorn hen was characterized. The tumor had the characteristics of a fibro- or myxofibrosarcoma and was maintained by transplantation in chicks over a period of several years. Cell-free extract from the tumor produced tumors at the site of inoculation after sc injection into 3-wk-old chicks. Type-C virus-like particles were observed in the extracellular spaces and vacuoles of the tumor cells. Inoculation with the original viral stock produced pocks on 10-day-old embryos and induced transformation of chick and quail embryo fibroblasts. The virus was designated Yamaguchi 73 sarcoma virus (Y73). The virus showed the host range and interference patterns of subgroup A with a possible minor subgroup E component. Cloned virus had the same envelope characteristics as uncloned virus. The replicating capacity of Y73 suggested that it was defective, and this was supported by the infectious center assay. The defectiveness could not be defined. (19 refs)

- 79-0956 Proviruses of Avian Sarcoma Virus Are Terminally Redundant, Co-extensive with Unintegrated Linear DNA and Integrated at Many Sites.** (Eng) Hughes, S. H. (Dept Microbiology, Univ. California, San Francisco, CA, 94143); Shank, P. R.; Spector, D. H.; Kung, H. J.; Bishop, J. M.; Varmus, H. E.; Vogt, P. K.; Breitman, M. L. *Cell* 15(4): 1397-1410; 1978.

The DNA from 15 clones of avian sarcoma virus (ASV)-transformed normal rat kidney cells was analyzed with restriction endonucleases and molecular hybridization techniques to determine the location and structure of proviral DNA. Each of the 20 complete or incomplete proviruses studied appeared to be located in a different site in cellular DNA, and at least 10 were located in regions separated by more than 10⁷ daltons. Two of the original 15 clones contained proviral DNA located at two distinct sites in the host cell DNA. These proviruses appeared to be identical to the single proviruses observed in six other clones. Seven clones contained at least one unit of abnormal viral DNA integrated into the host genome. Three of the four anomalous proviruses analyzed were deletion mutants lacking 25%-65% of the genetic content of ASV; the fourth was normal but for a novel site for cleavage by *Eco*RI. Both ends of at least 18 proviruses contained sequences specific to both the 3' and 5' termini of viral RNA. The organization of these terminally redundant sequences appeared identical to that of the 300 base pair re-

peats previously found at the ends of unintegrated linear DNA. Thus, proviral DNA is coextensive, or nearly coextensive, with unintegrated linear DNA and has a structure denoted as CELL DNA-3'5'-----3'5'-CELL DNA. (48 refs)

79-0957 Characterization of a Normal Avian Cell Protein Related to the Avian Sarcoma Virus Transforming Gene Product. (Eng) Collett, M. S. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Brugge, J. S.; Erikson, R. L. *Cell* 15(4): 1363-1369; 1978.

A normal avian cell protein antigenically related to the pp60src viral protein responsible for transformation by avian sarcoma virus (ASV) was identified by immunoprecipitation of uninfected chicken, duck, quail, and pheasant cells with serum from marmosets bearing ASV-induced tumors. In each avian species tested, the normal cell protein was a 60,000-daltons phosphoprotein (pp60) that was not related to any of the ASV structural proteins. However, preadsorption of the antiserum with cell extracts containing pp60src prevented immunoprecipitation of pp60. The chymotryptic peptides generated by partial proteolysis of pp60 and pp60src were very similar, except that one of the major peptides of pp60 showed an altered mobility. The phosphopeptide maps of pp60src and pp60 differed completely. Regardless of cellular growth conditions, the level of pp60 was approx thirty- to fiftyfold lower than that of pp60src in ASV-infected cells. The normal cell protein appeared to be functionally dissimilar to pp60src in that it lacked detectable protein kinase activity. (20 refs)

79-0958 Mapping Unintegrated Avian Sarcoma Virus DNA: Termini of Linear DNA Bear 300 Nucleotides Present Once or Twice in Two Species of Circular DNA. (Eng) Shank, P. R. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Hughes, S. H.; Kung, H. J.; Majors, J. E.; Quintrell, N.; Guntaka, R. V.; Bishop, J. M.; Varmus, H. E. *Cell* 15(4): 1383-1395; 1978.

Physical maps of the DNA's of several strains of avian sarcoma virus (ASV) were constructed. On infection of permissive quail cells with ASV, a linear DNA was synthesized in the cytoplasm and three major species of viral DNA were synthesized in the nucleus: a form indistinguishable from the linear cytoplasmic species; closed circular DNA; and proviral DNA inserted covalently into the genome of the host cell. The linear DNA appeared to be a structure with a large (approx 300 base) natural repeat at both termini (eg, 3'5'-----3'5'). Two closed circular species of approx monomeric size were identified. The less abundant species contained all the sequences identified in the linear DNA, including two copies in tandem of the 300 nucleotide 3'5' repeat. The major species lacked about 300 base pairs mapped to the region of the repeated sequence. Thus it presumably contains only a single copy of that sequence. (50 refs)

79-0959 An Avian Oncovirus Mutant (SE 21Q1b) Deficient in Genomic RNA: Biological and Biochemical Characterization. (Eng) Linial, M. (Div. Oncology, Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA, 98104); Medeiros, E.; Hayward, W. S. *Cell* 15(4): 1371-1381; 1978.

The isolation and characterization of a coordinately defective (cd) mutant of Rous sarcoma virus (RSV) that is deficient in packaging of genomic RNA is reported. The RSV-transformed quail cells that shed the mutant virus (SE 21Q1b) contained all three functional messenger RNA (mRNA) classes in approx the same amounts present in wild-type virus-infected cells. In addition, the mutant virus was not deficient in any of the four known viral gene products, *gag*, *env*, *pol*, or *src*. However, less than 1% of the RNA in the virus particles released from the quail cells was virus-specific, and no functional 39S genomic RNA could be detected in the SE 21Q1b virions. Instead, the virions contained primarily a heterogeneous population of cellular RNA's. These results and data from superinfection experiments suggest that transcription and translation of viral RNA are normal in 21Q1b cells, but that some defect in the 21Q1b integrated genome prevents efficient packaging of the 39S RNA into virions. The nature of the defect may be complex and involve both genome structure and virus-coded factor(s). (34 refs)

79-0960 Metabolism of Acetylcholine Receptor in Chick Embryo Muscle Cells: Effects of RSV and PMA. (Eng) Miskin, R. (Lab. Chemical Biology, Rockefeller Univ., New York, NY, 10021); Easton, T. G.; Maelicke, A.; Reich, E. *Cell* 15(4): 1287-1300; 1978.

The effects of phorbol myristate acetate (PMA) and transformation by a temperature-sensitive mutant of Rous sarcoma virus (RSV) on the steady-state concentration, synthesis, and degradation of the nicotinic acetylcholine receptor (AChR) in chick embryo muscle cells were studied. In normal muscle cell cultures, the synthesis and degradation rates of AChR decreased systematically with the age of the cultures, and the rates could be manipulated by changes in the composition of the culture medium. Transformation by RSV increased the rate of AChR degradation, leading to a reduction in the surface receptor concentration. PMA also increased the rate of receptor degradation and decreased the rate of synthesis, greatly reducing the steady-state level of surface AChR. The muscle cell system allows quantitative measurement of an integral membrane protein and its metabolism, and it may serve as a more general model for studies of transformation-associated alterations in membrane and surface receptor metabolism. (36 refs)

79-0961 Lactate Dehydrogenase Isozymes in Rous Sarcoma and Muscle Tissue of Tumor-bearing Chickens. (Rus) Parina, E. V. (State Univ., Kharkov, USSR);

Mikhailova, S. A.; Antonov, V. S. *Ukr Biokhim Zh* 50(6): 706-710; 1978.

The distribution of various lactate dehydrogenase (LDH) isozymes was studied in 40-day-old chicks and adult hens infected with Rous sarcoma virus (0.2 ml of tumor suspension, im). On days 6, 10, and 14 after infection, the birds were sacrificed, and tumor and muscle tissue specimens were subjected to electrophoresis in polyacrylamide gels. In the chicks, changes in the isozyme spectrum of the tumor could be detected on day 14 (increased level of LDH5 and decreased levels of LDH1 and LDH2); in the adult hens, similar changes could be detected on day 6. Development of the Rous sarcoma affected the LDH spectrum in the intact (contralateral) muscle: the adult hens showed a decrease in LDH1 and LDH2 levels on days 10 and 14, compared with day 6 in the chicks. (7 refs)

79-0962 In Vitro Synthesis of Infectious Transforming DNA by the Avian Sarcoma Virus Reverse Transcriptase. (Eng) Clayman, C. H. (Dept. Microbiology, Univ. Minnesota Medical Sch., Minneapolis, MN, 55455); Mosharrafa, E.; Faras, A. J. *J Virol* 29(1): 242-249; 1979.

Infectious DNA molecules capable of transforming chicken embryo fibroblasts can be synthesized by Rous sarcoma virus (RSV)-associated reverse transcriptase in vitro under reaction conditions that facilitate a max yield of genome length DNA transcripts (approx 7.5-10 kilobases). Analysis of the DNA product synthesized by detergent-disrupted RSV under these conditions indicates that DNA complementary to viral RNA (minus-strand DNA) is genome length in size, whereas DNA complementary to genome length minus-strand DNA (plus-strand DNA) appears as subgenomic-length molecules that are 300-3,500 nucleotides long. These features of the DNA product synthesized by RSV reverse transcriptase in vitro are similar to those identified in the cytoplasm of cells shortly after infection and lend credence to studies of the mechanism of reverse transcription in vitro and their significance to proviral DNA synthesis in vivo. (31 refs)

79-0963 Integration of Rous-associated Virus Type 0 Provirus in Susceptible Chicken Cells. (Eng) Hefti, E. (Dept. Pathology, Univ. Chicago, Chicago, IL, 60637); Baluda, M. A. *J Virol* 29(1): 409-412; 1979.

This study was made to determine whether the concentration of endogenous proviral sequences per cell remains constant after in vitro cell culture and whether additional Rous-associated virus type 0 (RAV-0) proviruses can integrate after superinfection of susceptible cells. The number of viral genome equivalents per haploid cell genome was determined in normal chicken embryos from three selected chicken lines and in cultured fibroblasts (CEF) from these embryos. The cellular concentration of endogenous proviral DNA was

similar in embryos from chickens of lines SPAFAS, 7, 15, 7 x 15, and 100. The concentration of proviral DNA was not affected by in vitro cultivation in CEF from lines that do not spontaneously produce virus nor in CEF from line 7, which lacks receptors for RAV-0. There was, however, a restricted increase in the number of integrated proviral genome equivalents in CEF from line 7 x 15, which produces RAV-0 and can support replication of this virus, and in CEF from line 15 experimentally infected with RAV-0. Thus, additional RAV-0 proviral sequences can be integrated in cells with appropriate surface receptors, ie, of a phenotype other than C/E, but in nonproducing or C/E cells, the proviral DNA concentration remains constant during in vitro culture. (18 refs)

79-0964 Extracellular Cleavage of the Glycoprotein Precursor of Rous Sarcoma Virus. (Eng) Klemenz, R. (Swiss Inst. Experimental Cancer Res., 1066 Epalinges, Switzerland); Diggelmann, H. *J Virol* 29(1): 285-292; 1978.

The kinetics of the cleavage of pr92gp, the high-mol-wt precursor of the two glycoproteins (gp85 and gp35) of Rous sarcoma virus, were followed to determine the site of cleavage. The viral glycoproteins were detected by immunoprecipitation with anti-gp85 and anti-gp35 serum. Pulse-chase experiments showed that little or no intracellular cleavage of the precursor took place during the time in which most of the newly synthesized viral glycoprotein was exported from the cells. Soon after its synthesis, however, pr92gp underwent some modification that made it migrate slightly faster on sodium dodecyl sulfate-polyacrylamide gels. Under steady-state conditions, the precursor was the predominant form of intracellular viral glycoprotein. Virus that was harvested every 2 min from infected cells prelabeled for 90 min with ³H-mannose contained mostly uncleaved and only a little mature glycoprotein. By incubation of this freshly released virus in serum-free buffer, the majority of the glycoprotein precursor could be cleaved into mature gp85 and gp35. Virus harvested every 10 min contained only mature glycoproteins. Thus, almost all cleavage of the glycoprotein precursor takes place extracellularly, in newly budded virus particles. (35 refs)

79-0965 Recombination Between Viral and Cellular Sequences Generates Transforming Sarcoma Virus. (Eng) Wang, L. H. (Rockefeller Univ., New York, NY, 10021); Halpern, C. C.; Nadel, M.; Hanafusa, H. *Proc Natl Acad Sci USA* 75(12): 5812-5816; 1978.

The genomic RNA sequences of recovered avian sarcoma viruses (rASV's), their parental transformation-defective (td) viruses, and the Schmidt-Ruppin strain of Rous sarcoma virus subgroup A (SR-A) were characterized and compared by oligonucleotide (ON) fingerprinting. Special emphasis was placed on their *src*-specific sequences. Of six sarcoma-specific

ON's present in SR-A RNA, three to six were missing in the RNA's of the four td mutants examined. All six isolates of rASV had regained these six ON's. In addition, most rASV RNA's had three new ON's not present in the RNA of the td mutants or of SR-A. The newly obtained ON's were located between 800 and 2,600 nucleotides from the 3' end of rASV RNA, a region that corresponds to the *src* region of SR-A RNA mapped previously. Furthermore, the viral RNA's of two td mutants isolated from a clone of rASV lacked most *src*-specific ON's, including the three new ones. There were no differences among the RNA's of td, SR-A, and rASV in the regions outside of *src*. Thus, RNA sequences that rASV's have acquired from cells in the process of conversion from a td to a transforming virus are mapped within the *src* region and segregate with the transforming function. Some of the sequences are new and some are identical with those in SR-A RNA. The results strongly suggest that rASV's have been generated by recombination between td viral and cellular *src* sequences that have been identified in normal chicken and other avian cells. It is possible that different ASV's may have a common (cellular) origin for their *src* genes. (26 refs)

79-0966 Relationship Between Phase of Mitotic Cycle of Human Embryo Cells and Transformation with

Rous Sarcoma Virus and Polyoma Virus. (Rus) Karazhas, N. V. (Dept. Tumor Etiology and Diagnosis, Inst. Epidemiology and Microbiology, Moscow, USSR); Shevliagin, V. I. *Tsitologiya* 20(12): 1413-1418; 1978.

The susceptibility of human embryo cells during different phases of mitosis to transformation with Rous sarcoma virus (RSV) and polyoma virus (PV) was evaluated. Synchronized cell suspensions were contaminated with RSV or PV together with Sendai virus. The mitotic cycle of the human fibroblasts lasted 18 hr. Of five cultures infected with RSV during the S phase, four showed transformation 2-3 wk after infection (compared with 2/5 cultures infected during G₂ and 0/5 infected during G₁). Of seven cultures infected with PV during S, two showed transformation 2-3 wk after contamination (compared with 0/7 cultures infected during G₂ or G₁). (11 refs)

79-0967 Changes in Rous and Polyoma Viruses During Their Synthesis in the Cells of Unnatural Hosts.

(Rus) Karazhas, N. V. (Lab. Virus Etiology Tumors, N. F. Gamaleia Inst. Epidemiology and Microbiology, Moscow, USSR); Bykovskii, A. F.; Cherepantseva, E. A.; Chizhevskaya, V. I.; Shevliagin, V. I. *Biull Eksp Biol Med* 86(12): 710-713; 1978.

An attempt was made to overcome intraspecies virus specificity and to evaluate the possibility of the synthesis of oncogenic viruses in heterologous cells. The morphological and karyological properties of human embryo-derived continuous cell lines transformed by Rous sarcoma virus (RSV)

(line 23) or by polyoma virus (line P-2) were analyzed. The presence of RSV in cells of line 23 was shown by complement fixation reaction, immunofluorescence assay, and electron-microscopic examination. RSV cultivated in the human embryo cells retained the ability to transform chick embryo cells (natural host), but showed increased affinity for mammalian tissues. Similar results were obtained for polyoma virus cultivated in P-2 cells. (11 refs)

79-0968 Differential Mortality and Lesion Responses to Reticuloendotheliosis Virus Infection in

Marek's Disease-resistant and Susceptible Chicken Lines. (Eng) Scofield, V. L. (Hopkins Marine Station, Stanford Univ., Pacific Grove, CA, 93950); Spence, J. L.; Briles, W. E.; Bose, H. R. *Immunogenetics* 7(2): 169-172; 1978.

The mortality patterns and lesion responses of line N (Marek's disease-resistant) and line P (Marek's disease-susceptible) chickens infected with reticuloendotheliosis virus (REV) were compared to investigate the possibility of genetic control of tumorigenesis in the REV system. Chickens of line N (B-locus genotype *B¹/B¹*) and line P (*B⁰/B⁰*) were hatched on the same day and inoculated ip with REV (5 x 10³ plaque-forming units) at age 3.5 wk. Five of nine line N chickens died 12-16 days after infection with prominent hepatosplenomegaly. Eight of the 10 line P chickens died, 3 within 20 days of infection (all negative for visceral lesions) and the others 24-44 days after infection. Visceral lesions were present at death in 2/8 line P chickens. Thus, line N and P chickens respond differently to tumorigenesis by REV on the basis of lesion incidence and mortality patterns. From these results and those of previous studies, it is concluded that the overall resistance to tumorigenesis by the several oncogenic viruses in chickens is polygenic and controlled by loci within and outside of the major histocompatibility complex. (21 refs)

79-0969 Enhanced Oncornavirus Expression in Marek's Disease Tumors from Specific-Pathogen-Free

Chickens. (Eng) Campbell, W. F. (Dept. Microbiology, Mayo Clinic, Rochester, MN, 55901); Frankel, J. W. *J Natl Cancer Inst* 62(2): 323-328; 1979.

The recovery of an oncornavirus from cell cultures derived from kidney tumors induced in 4-day-old SPAFAS chickens by intraabdominal inoculation with 100 focus-forming units of Marek's disease herpesvirus (MDHV) is described. MDHV-inoculated chickens demonstrated increasing levels of infectious avian leukosis virus (ALV) RNA in kidney, ovary, and spleen tumors compared with control kidney, liver, and spleen tissue. DNA from these cultured kidney tumor cells annealed to an ALV complementary DNA probe at the same rate and exhibited the same extent of homology as DNA from cultured kidney cells, indicating the absence of exogenous ALV proviral sequences. Radioimmunoassay indicated that, like the vertically transmitted endogenous ALV of sub-

group E, these oncornaviruslike particles replicated in permissive turkey embryo fibroblast (TEF) culture, but not in nonpermissive chicken embryo fibroblast (CEF) culture of the C/E phenotype. These oncornavirus particles served as a helper virus to form Rous sarcoma virus pseudotypes, which produced foci in TEF cultures but not in C/E CEF cultures. The expression of endogenous or exogenous oncornaviruses should not be excluded as a contributory factor in the development of Marek's disease, Burkitt's lymphoma, or other human neoplasms with which herpesviruses have been associated. (46 refs)

- 79-0970 Avian Oncovirus Mill Hill No. 2: Pathogenicity in Chickens.** (Eng) Alexander, R. W. (Diagnostic Electron Microscopy Lab., Veterans Admin. Hosp., Gainesville, FL, 32602); Moscovici, C.; Vogt, P. K. *J Natl Cancer Inst* 62(2): 359-366; 1979.

The transforming and oncogenic effects of Mill Hill No. 2 (MH2), an avian C-type oncovirus, were studied by intraabdominal, iv, and sc injection into chickens of phenotypes C/E, C/CE, and Q/BC, and resulting tumors were studied by light and electron microscopy. MH2 induced leukemias and soft-tissue sarcomas, but the most striking pathogenic effect of this virus was production of carcinomas in the liver and kidney. The iv route was the most effective, giving rise to a higher percentage of birds with liver and kidney carcinoma, sometimes as early as 1 wk after injection. For example, of 50 C/E chickens inoculated iv with 2×10^3 focus-forming units, there were 28 hepatomas, 20 nephroblastomas, 6 lymphomas, and 3 sarcomas. A subgroup A MH2 pseudotype with Rous-associated virus type 3 as helper [MH2 (RAV-3)] induced substantial numbers of solid tumors, and, unlike standard MH2, also produced a high incidence of an acute unclassified leukemia. Helper viruses naturally associated with MH2 (MH2AV) produced only lymphomas, at a low incidence. The soft-tissue sarcomas produced at the injection site were composed of undifferentiated round cells, and a definite tissue of origin could not be determined. In the kidney, adenocarcinoma-like tumors with a malignant stroma were present. Hepatocarcinomas were the dominant tumors found in the liver. The undifferentiated lymphomas produced by MH2AV were composed of round cells and were highly malignant. These studies showed that MH2 has high oncogenic potential. The tumors induced by MH2 and myelocytomatosis virus MC29 are compared. (33 refs)

- 79-0971 The N-Terminal Sequence of Three Coat Proteins of Foot-and-Mouth Disease Virus.** (Eng) Strohmaier, K. (Bundesforschungsanstalt für Viruskrankheiten der Tiere, Tübingen, W. Germany); Wittmann-Liebold, B.; Geissler, A. W. *Biochem Biophys Res Commun* 85(4): 1640-1645; 1978.

The N-terminal sections of the sequences of the three coat

proteins VPgly, VPasp, and VPthr of foot and mouth disease virus (FMDV) were determined and compared with the first 10 amino acids of the corresponding Mengo virus proteins. In the proteins of the two viruses beginning with aspartic acid, 5/10 amino acids were found to be in identical positions. This suggests that the VPasp-proteins of both viruses are related. (17 refs)

- 79-0972 Properties of Morphologically Variant Haploid Frog Cells Formed by Combined Treatment with Mengo Virus and the Polyene Antibiotic Mediocidin.** (Eng) Fisher, P. B. (Wistar Inst. Anatomy and Biology, Philadelphia, PA, 19104); Goldstein, N. I.; Bryson, V. *In Vitro* 14(12): 961-965; 1978.

ICR 2A cells (haploid frog cells), ICR 2A M cells (3 cloned populations of ICR 2A cells resistant to 5 μ g/ml of the polyene antibiotic mediocidin), and ICR 2A M/MV cells (5 cloned populations of morphologically variant haploid frog cells produced by exposure of ICR 2A cells to mediocidin and Mengo virus) were compared with respect to surface glycoproteins, concanavalin A (Con A) agglutinability, and growth properties in liquid media. The ICR 2A M/MV cells contained an apparently high-mol-wt surface glycoprotein not found in ICR 2A or ICR 2A M cells and exhibited a higher degree of agglutinability in Con A, a higher plating efficiency, and a shorter population doubling time at 23 C than did ICR 2A or ICR 2A M cells. α -Methyl glucoside and α -methyl mannoside prevented the Con A agglutination of all cell lines. The differences exhibited between ICR 2A M/MV cells and the parental cells suggest that alterations resembling transformation had occurred in the former as a result of combined treatment with mediocidin and Mengo virus. (16 refs)

- 79-0973 Differential Expression of Poly (A)-adjacent Sequences of Mammary Tumor Virus RNA in Murine Mammary Cells.** (Eng) Dudley, J. P. (Dept. Microbiology, Univ California Sch. Medicine, San Francisco, CA, 94143); Rosen, J. M.; Butel, J. S. *Proc Natl Acad Sci USA* 75(12): 5797-5801; 1978.

Two complementary DNA (cDNA) probes were used to study mouse mammary tumor virus (MMTV) gene expression in several BALB/c mammary tumor cell lines, in normal lactating BALB/c tissue, and in a cloned C3H tumor cell line. cDNA primed by random calf thymus DNA oligodeoxynucleotides was representative of the entire MMTV genome, but cDNA primed by (dT)12-18 had a decreased genetic complexity and hybridized predominantly with poly(A)-adjacent sequences at the 3' end of MMTV RNA. These probes were characterized with respect to rates of hybridization with template RNA, size (as determined by alkaline sucrose gradient centrifugation), and thermal stability of the cDNA-MMTV RNA hybrids. The ability of these probes to protect

¹²⁵I-labeled MMTV RNA or ¹²⁵I-labeled poly(A)-adjacent MMTV RNA sequences from S₁ nuclease digestion was also determined. Hybridization studies indicated that there were approx 20 times more oligo(dT)-primed sequences in BALB/c lactating glands than there were sequences representing the entire genome, but in BALB/c tumor cells the ratio of oligo(dT)-primed to calf thymus-primed cDNA sequences was reduced to approx 4:1. In virus producer C3H tumor cells, there was only a twofold excess of oligo(dT)-primed sequences over that detected with a representative cDNA. These results are consistent with the existence of subgenomic viral messenger RNA (mRNA) species, integration of partial proviral copies, or differential mRNA processing in virus nonproducer and producer cells. 79-0974 Large-Scale Production of Mouse Mammary Tumor Virus in the Absence of Endogenous Murine Leukemia Virus. (Eng) Benton, C. V. (Viral Oncology Program, NCI, Frederick Cancer Res. Center, Frederick, MD, 21501); Harshman, J. S.; Robinson, O. R.; Shibley, G. P. *Appl Environ Microbiol* 37(1): 148-158; 1979.

The large-scale production and purification of mouse mammary tumor virus (MMTV) in the absence of detectable endogenous murine leukemia virus (MuLV) is reported. Mm5mt/c₁ (Mm5) cells, which were established from a C3H mouse adenocarcinoma, were used. Frozen Mm5 cultures of the same passage were cultured using a scale-up scheme, and dexamethasone was incorporated into the growth medium at the final passage. Max virus expression was observed by the third or fourth harvest, coincident with monolayer confluency. Harvests were stored at 4 C and then pooled prior to virus purification in 38% sucrose and 34% sucrose. A 1,000-fold concentration of MMTV particles and an approx 16,000-fold reduction in total protein were thereby achieved. Expression of endogenous Mm5 MuLV was increased by completely dispersing the Mm5 cells into single cell suspensions and by constantly agitating the suspensions before seeding. The cells were then stressed by rapid passage at low split ratios and elevated temperature. A three-step sucrose gradient was used to separate MMTV particles, which banded at densities from 1.17 to 1.21 g/cm³, from MuLV particles, which banded at densities from 1.13 to 1.17 g/cm³. Competition radioimmunoassay was the most sensitive method for detecting and quantitating MuLV in MMTV preparations. Over 25,000 liters of MMTV-containing Mm5 fluids have been produced from 22 production runs, and after purification and concentration, >225 product lots have been found to be free of detectable MuLV while containing high levels of MMTV. (30 refs)

79-0975 Rigid Plasma-Membrane-derived Vesicles, Enriched in Tumour-associated Surface Antigens (MLr), Occurring in the Ascites Fluid of a Murine Leukemia (GRSL). (Eng) van Blitterswijk, W. J. (Div. Cell Biolo-

gy, Antoni Van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam, The Netherlands); Emmelot, P.; Hilkmann, H. A.; Hilgers, J.; Feltkamp, C. A. *Int J Cancer* 23(1): 62-70; 1979.

The extracellular membranes (ECM) of thymus-derived spontaneous murine (GR/A strain) leukemia (GRSL) cells were purified and compared with plasma membranes isolated from a GRSL cell homogenate. The protein-phospholipid ratio and the specific sialic acid, 5'-nucleotidase, and mammary tumor virus-induced antigens (MLr) levels were markedly higher in the ECM than in the plasma membranes. The ECM also showed a 3-fold increase in the cholesterol-phospholipid molar ratio and a 10-fold increase in sphingomyelin content compared with the plasma membranes. It appeared that the extracellular material contained only random cell debris very shortly after inoculation of GRSL cells into syngeneic mice. With time, however, ECM survived or arose anew and showed a higher lipid microviscosity than either the subcellular fractions or purified plasma membranes obtained from whole cells. The data indicate that ECM are clearly derived from the cell surface of living cells. (38 refs)

79-0976 Tryptic Peptide Analysis of gag Gene Proteins of Endogenous Mouse Type C Viruses. (Eng) Albino, A. (Sloan-Kettering Inst., New York, NY, 10021); Korngold, L.; Mellors, R. C. *J Virol* 29(1): 102-113; 1979.

The internal viral proteins of known endogenous mouse C-type viruses were analyzed and compared with the use of tryptic peptide mapping. Tryptic digests of the internal proteins p30, p15, p12, and p10 of mouse xenotropic, ecotropic, and amphotropic C-type viruses were subjected to cation-exchange chromatography. Analysis of these maps revealed that the p30 proteins from representative isolates of all three viral subgroups were distinguishable. The p15 proteins were all unique. The p12 proteins of NZB xenotropic and wild-mouse amphotropic viruses were not identical and yielded peptide maps remarkably different from that of the ecotropic virus. The p10 proteins of xenotropic and ecotropic viruses were identical and were dissimilar to that of the wild-mouse amphotropic virus. The results further delineate the interrelatedness and polymorphism of these gag gene proteins. (40 refs)

79-0977 Wild Mouse RNA Tumor Viruses: A Nongenetically Transmitted Virus Group Closely Related to Exogenous Leukemia Viruses of Laboratory Mouse Strains. (Eng) Barbacid, M. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD, 20014); Robbins, K. C.; Aaronson, S. A. *J Exp Med* 149(1): 254-266; 1978.

Prototype wild mouse C-type tumor viruses were characterized with respect to their genetic relationship to the mouse

cell and to known exogenous and endogenous viruses of laboratory mouse strains. Amphotropic viruses isolated from wild mice trapped in separate geographical areas were found to be biochemically and immunologically indistinguishable, whereas amphotropic and ecotropic viruses naturally infecting the same animal were found to be *env* gene variants. Molecular hybridization studies demonstrated that neither host range variant was endogenous to the *Mus musculus* genome, although each demonstrated partial nucleotide sequence homology. Wild mouse C-type viruses exhibited much closer molecular and antigenic relatedness to the exogenous virus subgroup (Friend, Moloney, and Rauscher murine leukemia virus) than to prototype endogenous viruses isolated from laboratory mice. The evidence indicates that exogenous mouse C-type viruses have been maintained in nature over a long period of evolution as a separate virus group, causative of tumors in mice by a mechanism solely involving their transmission as infectious agents. (48 refs)

- 79-0978 Spontaneous Expression of Murine Endogenous Viruses in Hamster x Mouse Hybrid Cells.** (Eng) Park, S. S. (NCI-VA Medical Oncology Branch, NCI and Veterans Admin. Hosp., Washington, DC, 20422); Gazdar, A. F.; Lalley, P. A.; Minna, J. D.; Francke, U. *Int J Cancer* 23(1): 52-61; 1979.

The spontaneous expression patterns of murine leukemia virus (MuLV) from mouse spleen cultures and hamster x mouse spleen hybrid cells were compared. The hybrid cells preferentially segregated mouse chromosomes but retained a complete set of hamster chromosomes. None of 13 BALB/c spleen cultures expressed virus, whereas 6/20 hybrid clones expressed N-tropic or N- and X-tropic viruses. All AKR cultures and 5/7 hybrids expressed N-tropic but not X-tropic virus. All 6 NZB cultures and 5/8 hybrids expressed X-tropic virus, but virus expression did not occur in NIH Swiss or NIH Swiss/nude spleen or hybrid cultures. Mouse chromosome 7 was required, but not sufficient, for the initial expression of N-tropic virus; chromosome 2 may be necessary and sufficient for X-tropic virus release. The results indicate that spontaneous expression of MuLV strains does not require the followup MuLV-related genes: *Fv-1* (chromosome 4), *Fv-2* (chromosome 9), *Rec-1* (replication of ecotropic virus, chromosome 5), and *GV-1* and *H-2* (chromosome 17). (27 refs)

- 79-0979 Complexity and Abundance of Murine Leukemia Virus-related Nuclear and Messenger RNA Sequences in Mouse Embryo Cell Lines Which Are Differentially Sensitive to Carcinogen-induced Virus Activation.** (Eng) Getz, M. J. (Dept. Pathology and Anatomy, Mayo Clinic and Mayo Foundation, Rochester, MN, 55901); Elder, P. K.; Moses, H. L. *Cancer Res* 39(2, Part 1): 321-327; 1979.

The abundance and sequence complexity of endogenous murine leukemia virus (MuLV)-related nuclear and messenger RNA (nRNA and mRNA) sequences were determined in non-virus-producing AKR-2B cells derived from high-leukemia-incidence mice; in AKR-MCA cells, a chemically transformed virus-producing derivative; and in C3H/10T1/2 cells, derived from low-tumor-incidence mice. The polyribosome-associated, EDTA-released mRNA from AKR-2B cells contained MuLV-related sequences of lower complexity (as measured by hybridization with complementary DNA) than those found in the nucleus of the same cells. These MuLV-related sequences appeared to be of lower mol wt than the nuclear sequences and to contain only about 50% or less of the MuLV genomic complexity. In contrast, the steady-state nRNA isolated from both AKR-2B and AKR-MCA cells as well as the mRNA from AKR-MCA cells represented 100% of the MuLV genomic complexity, although the MuLV-related sequences in AKR-MCA mRNA were of lower mol wt than the AKR-MCA nRNA, sequences. The C3H/10T1/2 cells contained polysomal RNA and nRNA MuLV-related sequences of similar complexity (46% and 34%, respectively, of the total viral genome), revealing no posttranscriptional regulation at this level. Moreover, the hybridization assay revealed that the viral-specific RNA sequences in AKR and C3H cells shared a high degree of sequence homology. Although the complexity of the MuLV-related nRNA sequences was equivalent in AKR-2B and AKR-MCA cells, the relative abundance of the sequences was much greater in the AKR-MCA cells. The differences in the apparent complexity, abundance, and subcellular distribution of MuLV-related RNA sequences are consistent with the hypothesis that C3H cells maintain a more stringent control over the expression of endogenous MuLV-related genes than do AKR cells. The data also indicate that the nucleotide sequence complexity of endogenous C-type, viral-specific mRNA and nRNA can be regulated independently. (29 refs)

- 79-0980 Congenital Transmission of Murine Leukemia Virus from Wild Mice Prone to the Development of Lymphoma and Paralysis.** (Eng) Gardner, M. B. (Dept. Pathology, Univ. Southern California, Sch. Medicine, 2025 Zonal Ave., Los Angeles, CA, 90033); Chiri, A.; Dougherty, M. F.; Casagrande, J.; Estes, J. D. *J Natl Cancer Inst* 62(1): 63-70; 1979.

Experiments show that maternal congenital transmission of infectious murine leukemia virus, primarily via milk, is the major route of virus spread in Lake Casitas (LC) wild mice and in crosses of LC mice with uninfected wild and laboratory mice. An indirect extrachromosomal male transmission in utero of LC virus also readily occurred in matings of viremic LC males with C57L females, but apparently not with other uninfected wild or NIH Swiss females. Both amphotropic and ecotropic classes of LC murine leukemia viruses were potentially transmissible by congenital and venereal epigenetic means and could induce the same two diseases, lymphoma

and paralysis, that occur naturally in LC wild mice. Lymphoma and paralysis failed to occur in uninfected LC mice or in their hybrid progeny that escaped congenital infection. (48 refs)

79-0981 C-Type Virus Particles in Human Urogenital Tumours After Heterotransplantation into Nude Mice. (Eng) Wunderli, H. (Div. Urology, Dept. Surgery, Duke Univ. Medical Center, Durham, NC, 27710); Mickey, D. D.; Paulson, D. F. *Br J Cancer* 39(1): 35-42; 1979.

C-type virus particles formed in heterotransplants of 5/14 human urogenital tumors that had been serially transferred in NIH(S) nude mice were studied ultrastructurally. In most cases, the particles were found exclusively within the supporting connective tissue of the tumors. Peroxidase labeling with antimouse serum indicated that this connective tissue was of mouse origin. In one transitional-cell bladder carcinoma, C-type particles were detected in the connective tissue, the interspace between epithelial cells, and vacuoles between epithelial cells. Numerous particles were observed budding from epithelial cell membranes. Competition radioimmunoassays showed the presence of murine leukemia virus interspecies p30 antigen in extracts of the transplanted human tumors and in two spontaneous mouse tumors. No p30 antigens were found in tissues of mice that had not been used for heterotransplantation. The data suggest that endogenous nude mice viruses were activated by the human tumor grafts and that they subsequently infected the human tumor cells and formed particles. (24 refs)

79-0982 Redistribution and Modulation of Gross Murine Leukemia Virus Antigens Induced by Specific Antibodies. (Eng) Joachim, H. L. (Dept. Pathology, Lenox Hill Hosp., 100 E. 77th St., New York, NY, 10021); Sabbath, M. *J Natl Cancer Inst* 62(1): 169-180; 1979.

The modulation of Gross murine leukemia virus (G-MuLV)-induced rat leukemia cells (culture LT₁, from a leukemic thymus) by rat anti-G-MuLV antibodies was analyzed in vitro. Rat anti-G-MuLV antisera were added to the leukemia cell cultures for variable periods of time, and the redistribution of virus particles and membrane virus antigens was determined by electron microscopy, indirect immunofluorescence, and immunoelectron microscopy. LT₁ cells grown in medium with the antisera were generally larger, with more basophilic cytoplasm and large, regularly shaped nuclei that frequently had the appearance of immunoblasts. The cytoplasm occasionally included tubular structures, filaments, and multivesicular bodies. Virus particles and membrane virus antigens were redistributed in the form of polar patches and caps, and budding and detachment of virus particles were no longer seen. Substantial decreases in cytotoxicity indexes accompanied these changes. Cytotoxicity tests revealed an increased resistance to cytolysis when

fresh, nonheated rat serum was added to the heat-inactivated anti-G-MuLV rat serum. A heat-labile serum factor was apparently required for the in vitro promotion of cellular antigen modulation. This modulation paralleled similar changes obtained in vivo by transplantation of leukemia cells in rats with high anti-G-MuLV antibody titers. The importance of antigen modulation in this system concerns its direct relationship with the malignant potential of the leukemia cells. (37 refs)

79-0983 Gross Murine Leukemia Virus-induced Alterations in the Thymus of Preleukemic AKR Mice. (Eng) Beardsley, T. R. (Lab Nuclear Medicine and Radiation Biology, Warren Hall, Univ. California, Los Angeles, 900 Veteran Ave., Los Angeles, CA, 90024); Hays, E. F. *Cancer Res* 39(2, Part 1): 480-486; 1979.

Thymic morphology and thymocyte and T-cell function were studied in AKR mice to separate age-related structural and functional changes in the thymus from those caused by Gross murine leukemia virus (GMuLV). Newborn mice were inoculated ip at 3 days of age with either 0.1 ml of a 0.9% NaCl solution (AKR-N) or 0.1 ml cell-free filtrate containing GMuLV (AKR-V) and studied in the 5th wk of life. Both thymic wt and total thymic cell count were significantly decreased in AKR-V mice. The response of AKR-V thymocytes to both phytohemagglutinin (PHG) and alloantigen in mixed lymphocyte culture was significantly increased over that of normal thymic cells, as was graft-vs-host reactivity. Conversely, response to concanavalin A (Con A) was significantly decreased in the AKR-V thymocytes. Treatment with cortisone generally increased the reactivity of both groups of mice to PHG and Con A, and their responsiveness in the graft-vs-host reaction, accentuating the relationships already mentioned. Although AKR-V lymph node cells had a significantly higher background of thymidine uptake, the responses of T-cells from spleen and lymph nodes in all of these tests were otherwise generally similar. Reduction in the number of cortical cells responsive to Con A is suspected as the cause of thymic wt loss, while the relative increase in reactive cells caused by this cortical cell reduction may account for the increased reactivity to PHG and alloantigen in the thymus. (26 refs)

79-0984 Inhibitory Effect of Growth Hormone on Gross Passage A Virus-induced Thymus Leukemia in C3Hf Mice. (Eng) Duquesnoy, R. J. (Dept. Microbiology, Medical Coll. Wisconsin, Milwaukee, WI, 53201); Pedersen, G. M. *Cancer Res* 39(2, Part 1): 415-418; 1979.

The effect of growth hormone (GH) on Gross passage A (GPA) virus-induced leukemia was studied in C3Hf mice inoculated with ovine GH (potency, 0.86 IU/mg) starting the first week after birth (100 µg/day in week 1, 100 µg 3x/wk in weeks 2 and 3, 100 µg 2x/wk in weeks 4 and 5, and 100

$\mu\text{g/wk}$ until the age of 3 mo). Control mice received bovine serum albumin (BSA) injections or no injections at all. Half of the mice from all three groups received 0.2-ml sc injections of a 1:20 dilution of GPA virus extract on day 4 of life. The GPA virus-infected mice experienced a high incidence of lymphoid leukemia with a minimum latent period of 3 mo. The median survival time (MST) of the female mice was 225, 135, and 108 days, respectively, in the GPA-GH, GPA-BSA, and GPA-only groups; the MST of the male mice was 297, 178, and 162 days, respectively. Because the GPA-infected mice also developed salivary gland tumors in large numbers but noninfected controls did not, it was suspected that the GPA extract contained another tumor-inducing agent. The GPA-GH group exhibited a high mortality from salivary gland tumors after 7 mo of age, so that the enhancement of survival by GH might have been more significant than that observed. In the GPA-GH, GPA-BSA, and GPA-only groups, the leukemia mortality rate was 35%, 74%, and 80%, in females and 45%, 75%, and 89%, in males, respectively. Thus, GH treatment produced a significant reduction in mortality compared with the other two groups. All three groups of male GPA-infected mice and the GPA-BSA and GPA-only groups of female mice died predominantly with type A leukemia, whereas 50% of the GPA-GH female mice that died with leukemia had type-B tumors. Therefore, GH treatment of female mice can alter the nature of induced leukemias as well as delay their development. The results indicate that GPA virus-induced leukemia can be classified on the basis of thymus involvement (ie, type A with T-cell leukemia or type B with thymus-independent leukemia). (31 refs)

79-0985 Isolation and Characterization of a Tumor Cell Surface Antigen from Spontaneously Transformed BALB/c Mouse Fibroblasts. (Eng) Kamm, A. R. (Dept. Biochemistry, Coll. Medicine, Univ. Arizona, Tucson, AZ, 85724); Grimes, W. J. *Proc Natl Acad Sci USA* 75(12): 5912-5916; 1978.

The detection, isolation, and partial characterization of a cell-surface antigen on three cultured fibroblast cell lines derived from BALB/c mice are described. The antigen migrates as a polypeptide of approx 100,000 daltons in a discontinuous sodium dodecylsulfate-polyacrylamide gel electrophoresis system, can be labeled by metabolic incorporation of ^3H -glucosamine or by the ^{125}I /lactoperoxidase method, and can be isolated by concanavalin A affinity chromatography. It was shown to be antigenic in BALB/c mice, it is present on immunogenic transformants, and it appears to be correlated with the rejection of immunogenic tumor cells. This antigen also shares antigenic determinants with Moloney leukemia virus (MLV), as MLV-specific antiserum precipitated the 100,000-dalton protein from viral and immunogenic spontaneous transformants. This virus-related antigen comigrated with the major iodinated cell-surface protein of these transformants. Sera taken from mice bearing immunogenic tumors contained cell-surface-directed antibodies against the

tumor cells. Rabbit antiserum to the purified antigen demonstrated a marked preference for the surfaces of immunogenic tumor cells vs normal cells or nonimmunogenic tumor cells. (24 refs)

79-0986 The Effect of pH on the Infectivity and Production of Murine Retroviruses. (Eng) Walker, J. R. (Dept. Biological Sciences, Univ. Warwick, Coventry CV4 7AL, England); Avery, R. J. *FEMS Microbiology Letters* 5(1): 47-51; 1979.

Experiments demonstrating that the infectivity, production, and reverse transcriptase activity of murine sarcoma/leukemia virus are decreased by zwitterionic buffers at pH levels other than 7.4 are presented. The effect of pH at different temperatures was also studied. (8 refs)

79-0987 Phenotypically Distinct Target Cells for Murine Sarcoma Virus and Murine Leukemia Virus Marrow Transformation In Vitro. (Eng) Greenberger, J. S. (Joint Center Radiation Therapy, Dept. Radiation Therapy, Harvard Medical Sch., Boston, MA, 02115). *J Natl Cancer Inst* 62(2): 337-348; 1979.

The effects of isolates of Harvey, Moloney, and Kirsten murine sarcoma virus (H-, M-, and Ki-MuSV, respectively) on long-term cultures of NIH Swiss mouse bone marrow were determined, and the results were compared with those of the associated C-type helper virus alone. (Rauscher murine leukemia virus, R-MuLV, or Balb:virus-1). An in vitro hematopoietic microenvironment was established from explanted fragments of bone marrow with the use of corticosteroid-reconstituted horse serum. Infection with Ki-MuSV plus either helper virus coat reduced granulopoiesis and produced neoplastic transformation of macrophages and preadipocytes in the adherent cell population within 4-wk. Ki-MuSV-transformed, virus-releasing macrophages formed clusters of 4-49 cells in methylcellulose-containing medium in the absence of colony-stimulating factor (CSF), synthesized lysozyme, esterase-M, and CSF, and produced tumors on inoculation iv into adult NIH Swiss mice or ip into newborn NIH Swiss mice at 10^6 cells/mouse. Addition of H-MuSV or M-MuSV pseudotypes with R-MuLV helper virus also transformed macrophages and preadipocytes in the adherent cell population and decreased granulopoiesis. The induced macrophage cell lines were morphologically and histochemically indistinguishable from those induced by Ki-MuSV. In contrast, the helper viruses accelerated the proliferation of atypical granulocytes in the cultures. Over a 9-wk period, there were increasing numbers of atypical myeloblasts and promyelocytes that showed dyssynchronous nuclear-cytoplasmic maturation, basophilic granulation, cytoplasmic vacuolation, and formation of incompletely maturing CSF-dependent granulocyte-macrophage colonies in vitro and small spleen colonies in vivo. These data indicate

that there are phenotypically distinct biologic target cells for transformation by MuSV and MuLV in mouse marrow culture. (46 refs)

79-0988 "sarc" Sequence Transcription in Moloney Sarcoma Virus-transformed Nonproducer Cell Lines. (Eng) Bondurant, M. (St. Jude Children's Res. Hosp., Memphis, TN, 38101); Ramabhadran, R.; Green, M.; Wold, W. S. *J Virol* 29(1): 76-82; 1979.

³H-Labeled complementary DNA(sarc) that is complementary to the murine sarcoma virus (MSV)-specific portion of the Moloney MSV (M-MSV) genome was prepared and used as a hybridization probe to (1) analyze transcription of M-MSV-specific sequences and (2) determine the relative copy number of these sequences in the DNA of several M-MSV-transformed nonproducer cell lines derived from NIH 3T3 cells. M-MSV-specific RNA was quantitated in the cytoplasm of the three clonal NIH 3T3 cell lines 71 N CL 5, 71 N CL 6, and 71 N CL 3. By the criteria of cell morphology and agglutination by concanavalin A, CL 5 cells are highly transformed, CL 6 cells are almost normal in the sense that they resemble the parent NIH 3T3 cells, and CL 3 cells are phenotypically intermediate. The amounts of cytoplasmic MSV-specific RNA correlated well with the relative degrees of transformation of the cell lines, varying > 35-fold between the least transformed (CL 6) and most transformed (CL 5) lines. Superinfection of CL 5 or CL 6 with Moloney murine leukemia virus resulted in a fivefold increase in MSV-specific RNA in the cell cytoplasm. Evidence from ³H-labeled complementary DNA:cell DNA hybridization studies indicated that the quantity of M-MSV-specific RNA in the nonproducer lines was not directly related to DNA provirus copy number in the cell DNA. Although CL 5 and CL 6 differ greatly in transformation characteristics and in MSV-specific RNA content, they each apparently contain about two copies of MSV-specific DNA sequence per haploid genome. Thus, factors such as site of provirus integration may be of primary importance in determining virus-specific transcription and cell transformation. (30 refs)

79-0989 Radiation Induction of Endogenous Type C Virus from Mouse Cells Transformed In Vitro by Murine Sarcoma Virus. (Eng) Niwa, O. (Dept. Experimental Radiology, Faculty Medicine, Kyoto Univ., Sakyo-ku, Kyoto 606, Japan); Sugahara, T. *J Natl Cancer Inst* 62(2): 329-335; 1979.

Cell lines from AKR and BALB/c mouse embryos were compared for their sensitivity to x-ray induction of endogenous C-type virus. No virus activity was detected in AKR 2B cells or a secondary culture of AKR mouse embryo fibroblasts after 500 or 1,000 R of x-irradiation. In contrast, K-Balb cells, a Balb/3T3 cell line nonproductively transformed by Kirsten murine sarcoma virus, were sensitive to x-irradiation.

The number of cells with induced virus increased significantly at a dose as low as 50 R, which exerted almost no effect on cell survival. The induction frequency increased with increasing dose of x-rays up to 400 R. Only Balb:virus-2 was activated by x-irradiation, whereas both Balb:virus-1 and Balb:virus-2 were activated after treatment of K-Balb cells with 5-iodo-2'-deoxyuridine. UV light and 4-nitroquinoline 1-oxide (4-NQO) also induced virus expression in K-Balb cells. X-rays, UV light, and 4-NQO gave almost identical virus-induction frequencies of 3×10^{-4} . The virus-induction frequency for 5-bromo-2'-deoxyuridine was the highest, 9.4×10^{-2} . These results indicate that the molecular mechanisms for virus induction by halogenated pyrimidines and physical and chemical carcinogens may be different and that the damages responsible for virus activation by x-irradiation may be different from lethal damages. (37 refs)

79-0990 Isolation and Characterization of a Feline Sarcoma Virus-coded Precursor Polypeptide. (Eng) Khan, A. S. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Deobagkar, D. N.; Stephenson, J. R. *J Biol Chem* 253(24): 8894-8901; 1978.

A feline sarcoma virus (FeSV)-coded precursor polypeptide was isolated and characterized. FeSV pseudotype virions produced by superinfection of nonproductively transformed mink and rat cells efficiently incorporated the 130,000-mol-wt precursor polypeptide (FeSV Pr130) and several of its intermediate cleavage products, including a 25,000-mol-wt product containing feline leukemia virus (FeLV) p12 and p15 and a protein of 70,000 mol wt. FeSV Pr130 was highly acidic (pI 3.9) and was reactive in competition immunoassays for two FeLV gag gene-coded structural proteins (p15 and p12); it failed to compete for other FeLV-coded structural proteins or viral-coded reverse transcriptase. ¹²⁵I-labeled FeSV Pr130 was precipitated by high-titered goat serum against FeLV p15, p12, and, to a lesser extent, p30. Naturally immune cat serum with known high-titered antibody against the transformation-specific feline oncornavirus-associated cell membrane antigen (FOCMA) also precipitated Pr130 efficiently, even after extensive absorption with FeLV. The data indicate that Pr130 contains a nonstructural component corresponding to the 60,000-mol-wt FeSV-coded, FOCMA cross-reactive protein expressed in FeSV-transformed mink cells. A highly specific competition immunoassay for the structural component of FeSV Pr130 is described. (34 refs)

79-0991 Inhibition of Human Lymphocyte Mitogen and Antigen Response by a 15,000-Dalton Protein from Feline Leukemia Virus. (Eng) Hebebrand, L. C. (Dept. Veterinary Pathobiology, Ohio State Univ., Columbus, OH, 43210); Olsen, R. G.; Mathes, L. E.; Nichols, W. S. *Cancer Res* 38(2, Part 1): 443-447; 1979.

The immunosuppressive effects of a 15,000-dalton protein (p15) from a C-type feline leukemia virus (FeLV) on the peripheral blood lymphocyte (PBL) response of normal human subjects to several mitogens and antigens were studied by a lymphocyte blast transformation test. The PBL responses of 4/6 subjects were suppressed 70%-96% when the cells were exposed to 10.0 μg /well concanavalin A (Con A) in the presence of 5.0 μg of p15. Likewise, the response to 1.2 μg /well phytohemagglutinin was only 12%-40% that of control values in 3/5 subjects. The three subjects who responded to streptokinase-streptodornase (108 units/well) and 2/3 who responded to *Candida albicans* (0.05 ml/well) were suppressed 68%-91% when their PBL were cultured with 5.0 μg of p15. Immunosuppressive doses of 2.0 and 5.0 μg /well of p15 appeared to have no cytotoxic effect on the cultures, as no cell counts dropped below the original well count. The number of cap-forming lymphocytes induced by Con A decreased 51%-91% in the presence of 5.0 μg p15, as indicated by lymphocyte membrane studies with fluorescein isothiocyanate-Con A. Thus, a C-type virion protein can induce immunological dysfunction in vitro. (11 refs)

- 79-0992 Biochemical and Immunological Characterization of a Reverse Transcriptase from Human Melanoma Tissue.** (Eng) Chandra, P. (Gustav-Embsen-Zentrum der Biologischen Chemie, Abteilung für Molekularbiologie, Klinikum der J. W. Goethe-Universität, Theodor-Stern-Kai 7, D-6 Frankfurt 70, W. Germany); Balıkcıoglu, S.; Mildner, B. *Cancer Lett* 5(6): 299-310; 1978.

The reverse transcriptase (RT; RNA-directed DNA polymerase) from human melanoma tissue was purified and characterized biochemically and immunologically. Purification was accomplished by serial centrifugation of the filtered tissue homogenate to isolate the microsomal fraction of the cells, solubilization of this fraction, and then successive diethylaminoethyl cellulose (DE-23 and DE-52) and phosphocellulose column chromatography. The purified enzyme (mol wt 68,000) was most efficient in transcribing the synthetic primer templates (dG)₁₈(rC)n and (dG)₁₈(rC)n, followed by (dT)₁₂(rA)n. It also transcribed a 70S RNA from Rauscher leukemia virus, but it failed to transcribe (dT)₁₀(dA)n, indicating that the enzyme is free of DNA polymerase- β activity. Failure to utilize (dA)₁₂ and (dG)₁₈ as initiators showed that the RT did not contain any terminal deoxynucleotidyl transferase activity. The enzyme had a pH optimum of 8.0, an Mn²⁺ optimum of 0.6 mM, and a KCl optimum of 60 mM. Serological studies indicated that the RT was not antigenically related to DNA polymerases from simian sarcoma virus, avian myeloblastosis virus, Rauscher leukemia virus, and human myelofibrotic spleen. However, the human melanoma enzyme showed close antigenic similarity to the DNA polymerases from baboon endogenous virus and rhabdomyosarcoma virus RD-114, the endogenous virus of the cat. (19 refs)

- 79-0993 Infectivity Tests of Secretions and Excretions From Cattle Infected with Bovine Leukemia Virus.** (Eng) Miller, J. M. (U.S. Dept. Agriculture, Science and Education Admin., Federal Res., Natl. Animal Disease Center, P.O. Box 70, Ames, IO, 50010); Van Der Maaten, M. J. *J Natl Cancer Inst* 62(2): 425-428; 1979.

Secretions and excretions from cattle (Holstein-Friesian, Angus, Guernsey, and Simmental) with persistent bovine leukemia virus (BLV) infections were analyzed for BLV in a sheep bioassay to determine their relative importance as sources of virus for transmission in contact situations. Test sheep of a mixed breed were injected with the fluids, and infection was confirmed by development of antibody to the BLV glycoprotein antigen (detected by the agar gel immunodiffusion) and reisolation of virus from sheep peripheral blood WBC. The virus was detected in milk from 4/6 cows examined, one of which was from a commercial dairy. Likewise, the colostrum of 1/4 cows produced persistent positive results of virus infection in one test sheep. None of the sheep inoculated with semen from eight bulls or with nasal secretions, urine, or saliva from two cows developed BLV-precipitating antibodies. The presence of BLV in colostrum and milk indicates these materials may be potential sources of infection for nursing calves. Moreover, the presence of BLV infectivity in milk from a commercial dairy cow raises questions regarding the possible significance of this virus as a hazard to human health. (26 refs)

- 79-0994 Postnatal and Prenatal Transmission of the Bovine Leukemia Virus under Natural Conditions.** (Eng) Piper, C. E. (Hazleton Labs. America, Inc., 9200 Leesburg Turnpike, Vienna, VA, 22180); Ferrer, F. J.; Abt, D. A.; Marshak, R. R. *J Natl Cancer Inst* 62(1): 165-168; 1979.

The distribution of bovine leukemia virus (BLV) and BLV antibodies was studied in a well-characterized multiple-case leukemia herd (BF) of purebred Jersey cattle by the syncytia infectivity and virus neutralization antibody assays, respectively. Of 84 calves examined before their colostrum meal, only 15 were positive for BLV and/or BLV antibody. All 52 calves examined after colostrum ingestion and before age 5 mo had acquired maternal antibodies to BLV, but only 12 (all infected at birth) were positive for infectious BLV. These antibodies were transient, with only 15 animals (13 originally infected) being positive for antibody at 7-10. The incidence of BLV infection did not change significantly during the first 10 mo of life. In keeping with standard husbandry practices, calves were separated from the adult herd after weaning and kept apart up to 14-16 mo of age. Therefore, the rapid increase in BLV infection rate (93% of cases by age 24 mo) beginning at age 12-16 mo was assumed to result from contact with the exposed herd. Of 17 BLV calves born antibody-negative and raised in isolation to age 24 mo after being weaned from their BLV-infected dams, only 3 became BLV-positive, vs 17/17 animals in a control group that joined the herd at the normal time. These results indicate (1) that

prenatal transmission of BLV is infrequent; (2) that during the first weeks of life, calves are protected by milk-borne maternal antibodies from contact or milk-borne BLV infection; and (3) that BLV infection persists despite the presence of actively produced or passively acquired BLV-neutralizing antibodies. (18 refs)

79-0995 Noncondylomatous Wart Virus Infection of the Postmenopausal Cervix. (Eng) Laverty, C. R. (Dept. Pathology, King George V Hosp., Camperdown, New South Wales 2050, Australia); Booth, N.; Hills, E.; Cossart, Y.; Wills, E. J. *Pathology* 10(4): 373-378; 1978.

Noncondylomatous papilloma (wart) virus infection of the cervix is more common than heretofore realized. Although most of the patients are young, two cases in postmenopausal women were found, one with cytological evidence of persistence of the lesion for 12 yr. The two cases show that warty atypia must be considered in the interpretation of cytological atypia in postmenopausal women. (7 refs)

79-0996 Translation of Polyoma Virus T Antigens In Vitro. (Eng) Hunter, T. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); Hutchinson, M. A.; Eckhart, W. *Proc Natl Acad Sci USA* 75(12): 5917-5921; 1978.

The in vitro translation of polyoma virus-specific RNA isolated from the cytoplasm of infected mouse 3T6 cells during the late stage of infection produced three tumor (T) antigens with mol wts of approx 90,000 (90K), 60K, and 22K. The tryptic peptide patterns of these antigens were very similar or identical to the patterns of the corresponding proteins in polyoma-infected cells. Their ability to incorporate methionine from initiator transfer RNA in vitro showed that the NH₂ termini of all three primary translation products are retained in the mature molecules; ie, the antigens share common NH₂-terminal sequences. Polyoma complementary RNA (cRNA) coded for a protein that was slightly larger than but otherwise similar to the 22K T antigen, but it did not produce the 90K or 60K protein, which suggests that the generation of messenger RNA's (mRNA's) for these T antigens requires the removal of intervening sequences. The mRNA coding for the 90K T antigen was approx 280 nucleotides smaller than the RNA's coding for the 60K and 22K T antigens. The 60K T antigen may be translated partially in a different reading frame from sequences also coding for the 90 K T antigen. The demonstration that polyoma virus codes for three different T antigens with different functions and cellular locations raises the possibility that all three proteins play a role in cell transformation. (30 refs)

79-0997 Three Species of Polyoma Virus Tumor Antigens Share Common Peptides Probably near the

Amino Termini of the Proteins. (Eng) Smart, J. E. (Cold Spring Harbor Lab., P.O. Box 100, Cold Spring Harbor, NY, 11524); Ito, Y. *Cell* 15(4): 1427-1437; 1978.

The tryptic peptides of the three major tumor (T)-related proteins (100K, 55K, and 22K) from polyoma virus-infected mouse cells were studied following metabolic labeling with ³H-leucine, ³⁵S-methionine, and ³H-proline. The results indicated that there are at least five peptides that are shared by the three proteins, and that they are coded for by the region between 74 and 80 map units on the viral genome. Three peptides are shared by the 55K and 22K proteins, but not by the 100K protein; these peptides are probably derived from the region of the viral genome lying between about 80 and 85 map units. Three peptides were found only in the 22K protein; six were found only in the 55K protein; and sixteen were found only in the 100K protein. The genetic information for the unrelated peptides of the 100K and 55K proteins probably comes from the portion of the messenger RNA codes for the carboxy terminal portions of these molecules. These portions of the two proteins must differ considerably. The peptides unique to the 22K protein have also been tentatively assigned to the carboxy terminal region of the molecule. (24 refs)

79-0998 Polyoma Infected Cells Contain at Least Three Spliced Late RNAs. (Eng) Horowitz, M. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel); Bratosin, S.; Aloni, Y. *Nucleic Acids Res* 5(12): 4663-4675; 1978.

Poly(A)-containing polyoma cytoplasmic RNA hybridized to linear double-stranded polyoma DNA by displacing the part of the DNA strand identical to this RNA, and RNA displacement loops (R loops) were formed. Electron microscope examination of these structures showed that at least three late polyoma-specific RNA's were present and that the leader sequences at the 5' ends of these viral RNA's were not coded immediately adjacent to the bodies of the RNA's. The three RNA species may correspond to the 19S, 18S, and 16S viral messenger RNA's. Measurements of the R loops determined the locations of the bodies and leaders of the RNA's on the physical map of polyoma DNA, along with the length of the bodies, leaders, and corresponding intervening DNA sequences. 79-0999 Differential In Vitro Growth Properties of Cells Transformed by DNA and RNA Tumor Viruses. (Eng) O'Neill, F. J. (Dept. Microbiology, Univ. Utah, Salt Lake City, UT, 84132). *Exp Cell Res* 117(2): 393-401; 1978.

The in vitro growth properties of untransformed (UT) and RNA and DNA virus-transformed Syrian hamster, rat, and mouse cells were compared. Cells transformed by the DNA tumor viruses [simian virus 40 (SV40), adenovirus type 7 (Ad 7), and polyoma virus] grew to concentration densities that

LIBRARY U. OF I. URBANA - CHAMPAIGN

were markedly higher than those of UT cells or cells transformed by RNA tumor viruses (Kirsten or Moloney strains of murine sarcoma virus). However, the RNA virus-transformed cells grew to densities greater than those of UT cells. In most cases, SV40- and Ad7-transformed cells seemed smaller than UT or RNA virus-transformed cells, but the size differences, although significant, were not great enough to account for the apparent growth differences. As growing cultures of UT cells neared saturation density, the fraction of cells synthesizing DNA was minimal. The RNA virus-transformed cells were also contact-inhibited, but at a significantly higher density. In contrast, the DNA virus-transformed cells propagated to still greater densities and continued DNA synthesis at a high rate, even at very high densities. Thus, DNA virus-transformed cells are not contact-inhibited. Apparently, the ability of these cells to propagate to relatively higher densities is a reflection of an increased capacity to synthesize DNA at high densities. There were no consistent differences between the two transformed cell groups in ability to form colonies in agar, although 4/8 RNA virus-transformed lines produced colonies inefficiently or not at all. The observed differential growth properties might be applied to cultured human tumor cells. (32 refs)

79-1000 Origin of DNA Replication in Papovavirus Chromatin is Recognized by Endogenous Endonuclease. (Eng) Waldeck, W. (Institut für Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Fohring, B.; Chowdhury, K.; Gruss, P.; Sauer, G. *Proc Natl Acad Sci USA* 75(12): 5964-5968; 1978.

Evidence is given that up to 30% of the covalently closed circular DNA of simian virus 40 (SV40) and polyoma virus is cleaved in vitro to full-length linear rods by an endonuclease endogenous to isolated viral chromatin. The precise nature of this endonuclease is not known. It is not only bound to chromatin but also appears in free form in nuclear extracts. The cleavage takes place in viral chromatin either at or closely adjacent to the respective origins of DNA replication (\pm 75 base pairs). The positions of the cleavage sites were determined by aligning the different lengths of the cleavage products obtained after digestion with single-cut restriction endonucleases on the physical maps such that they started at the respective cleavage sites of the endonucleases. The full-length linear DNA rods whose ends map adjacent to the origin of DNA replication could also be isolated by sodium dodecyl sulfate/phenol extraction from both SV40-infected permissive cells and purified SV40 virions. Biological properties such as initiation of transcriptional activity may account for the structural specificity of the papovavirus chromatin in the region of the genome close to the initiation site of DNA replication. (32 refs)

79-1001 Synthesis of High Molecular Weight Antigen T of Virus SV40 in Paired Cell-free System of

Transcription-Translation. (Rus) Shtrauss, M. (Central Inst. Molecular Biology, Berlin, E. Germany); Emel'ianov, V. V.; Kalinin, V. N.; Shernek, Z.; Geissler, E.; Tikhonenko, T. I. *Vopr Virusol* (6): 669-673; 1978.

An attempt was made to synthesize tumor antigen (T antigen) in the paired cell-free transcription-translation system from *Escherichia coli* Q13 using DNA of virus SV40 as a template. Saturation of the system was observed at a DNA concentration of 6 $\mu\text{g}/\text{nl}$ (2×10^{-9} M): the yield of the protein (measured by the rate of ^{14}C -amino acid incorporation) was similar to that synthesized in the presence of a fivefold amount of plasmid ColEI DNA. Along with the relatively "short" T-antigen polypeptides, fragments with mol wt of 74 and 86 kilodaltons were found in the system, indicative of the complete expression of gene A. (23 refs)

79-1002 Surface Glycopeptide Change Triggered by Contact Between Normal Cells from Rat Liver and Their Simian Virus 40-Transformed Cells from the Same Virus. (Eng) Yokota, M. (Dept. Biological Products, Inst. Medical Science, Univ. Tokyo, P.O. Takanawa, Tokyo 108, Japan); Kato, I.; Onodera, K.; Kadosaka, T.; Aoi, Y. *J Natl Cancer Inst* 62(2): 305-312; 1979.

Surface glycopeptide (SGp) changes induced by mixed culture of normal and simian virus 40-transformed rat liver epithelial cells (WIRL-3 and SV40-WIRL-3) were investigated, along with the biologic responses of the two lines to SGp's derived from each line independently and from the mixed culture. SGp from the mixed culture showed, upon electrophoresis, a quantitative increase and a qualitative change in structure that was not detected in the SGp of normal and transformed cells cultured separately. These changes were ascribable mainly to normal cells responding to transformed cells, and a SGp change in WIRL-3 cells induced a qualitative SGp change in the SV40-WIRL-3 cells. Inhibition of ^3H -thymidine uptake of the cells by the three SGp preparations (each, 200 $\mu\text{g}/\text{ml}$ culture medium) was assessed to determine the activity of the Gp's in altering the function of the SV40-WIRL-3 cells. WIRL-3 cells were inhibited to essentially the same extent (30%) by all three Gp's, whereas SV40-WIRL-3 cells were inhibited 65% by the mixed-culture SGp, 50% by the WIRL-3 SGp, and 35% by its own SGp. From these results, it is hypothesized that the normal cell may have the ability to recognize, react with, and exert certain effects on transformed cells, with the glycocalyx playing a key role in this process. (14 refs)

79-1003 DNAs of Simian Virus 40 and Polyoma Direct the Synthesis of Viral Tumor Antigens and Capsid Proteins in Xenopus Oocytes. (Eng) Rungger, D. (Dept. Animal Biology, Univ. Geneva, CH 1224 Chene-Bourgeries, Geneva, Switzerland); Turler, H. *Proc Natl Acad Sci USA* 75(12): 6073-6077; 1978.

Experiments demonstrating that *Xenopus* oocytes transcribe and translate most or all of the genetic information contained in the simian virus 40 (SV40) genome are presented. SV40 large and small tumor antigens synthesized in the oocytes were indistinguishable, by both gel electrophoresis and ^{35}S -methionine-labeled tryptic peptide mapping, from the corresponding polypeptides synthesized in CV-1 African green monkey cells. The synthesis of large SV40 tumor antigen implies the correct splicing of its messenger RNA, which is complementary to nonadjacent nucleotide sequences in the early region of the viral genome. Polyoma DNA directed the synthesis of two polyoma tumor antigen polypeptides (57,000 M_r and small tumor antigen) and of the main capsid protein. (41 refs)

79-1004 Structure of Simian Virus 40 Chromosomes in Nuclei from Infected Monkey Cells. (Eng) Shelton, E. R. (Dept. Biological Chemistry, Harvard Medical Sch., Boston, MA, 02115); Wassarman, P. M.; DePamphilis, M. L. *J Mol Biol* 125(4): 491-514; 1978.

To avoid the appearance of potential artifacts in the study of the arrangement of nucleosomes in simian virus 40 (SV40) chromosomes, the isolation of SV40 chromosomes was avoided, and identical digestion conditions were maintained by incubating nuclei isolated from virus-infected CV-1 cells with micrococcal nuclease. This allowed a direct comparison between the structure of viral chromosomes and those of the host. To distinguish viral from cellular DNA fragments after electrophoresis in agarose gels, a previously described blotting-hybridization method was used. Cellular DNA was identified either by the same technique or by simply staining with ethidium bromide. While as many as 18 cellular DNA bands were detected in agarose gels, no more than 6 viral DNA bands were observed, and the viral DNA bands appeared broader and less well-resolved than the corresponding DNA bands from CV-1 chromatin. The av repeat distance between DNA oligomers from SV40 nucleosomes, 187 ± 11 base-pairs, was essentially the same as that observed for its host, 182 ± 6 base-pairs. These observations were independent of the extent of digestion and of the time after infection when nuclei were isolated. Since micrococcal nuclease digestion of SV40 chromosomes, both isolated and remaining in the nuclei, gave essentially the same results, the isolated chromosomes were not altered during their preparation. The results of these experiments, together with previously reported data, were used to construct a model for the arrangement of an av of 22 nucleosomes per genome in SV40 chromosomes that includes regions of nonnucleosomal DNA between some or all of the nucleosomes. (48 refs)

79-1005 Tandem Integration of Complete and Defective SV40 Genomes in Mouse-Human Somatic Cell Hybrids. (Eng) Campo, M. S. (Dept. Zoology, Univ. Edin-

burgh, Edinburgh EH9 3JT, Scotland); Cameron, I. R.; Rogers, M. E. *Cell* 15(4): 1411-1426; 1978.

The arrangement of simian virus 40 (SV40) DNA sequences integrated into human chromosome 7 was studied in two clones (Cl 10 and Cl 21) derived from mouse-human somatic cell hybrids: Cl 10 contained only one human chromosome 7 per cell, but Cl 21 contained an av of three. In the two clones, the integration site differed in both the host and the viral DNA. In Cl 10, the viral integration site lay close to position 0.37 in the early region of the SV40 genome; in Cl 21 DNA, it lay around position 0.7 to 0.8 in the late region of the viral genome. There was only one integration site in each clone. However, the viral DNA was integrated in more than one chromosome 7 in Cl 21 cells, the integration site being the same in all copies of chromosome 7 in these cells. In clone Cl 10, the integrated viral DNA had a complex arrangement of 6 tandem repetitions of complete and defective viral genomes. In clone Cl 21, there were 18 tandem repetitions of the viral genome. It is concluded that human chromosome 7 contains at least two different sites that can support the integration of SV40 DNA. (39 refs)

79-1006 Association of Simian Virus 40 T Antigen with Simian Virus 40 Nucleoprotein Complexes. (Eng) Mann, K. (Dept. Biology, Univ. Alaska, Anchorage, AK, 99504); Hunter, T. *J Virol* 29(1): 232-241; 1979.

The simian virus 40 (SV40) replicative intermediate (RI) DNA- or SV40 mature supercoiled (I) DNA-containing nucleoprotein (NP) complexes were examined for the presence of both the 100,000-dalton (100K) and 17K SV40 tumor (T) antigens. Viral NP complexes were extracted from the nuclei of SV40-infected TC7 cells by low-salt treatment in the absence of detergent, followed by sedimentation on neutral sucrose gradients. Two forms of SV40 NP complexes, those containing SV40 (RI) DNA and those containing SV40 (I) DNA, were separated from one another and were found to have sedimentation values of 125S and 93S, respectively. ^{35}S -methionine-labeled proteins in the NP complexes were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. In addition to VP1, VP3, and histones, a protein with a mol wt of 100K was present in the NP complexes containing SV40 (I) DNA. The 100K protein was confirmed as SV40 100K T antigen, both by immunoprecipitation with SV40 anti-T serum and by tryptic peptide mapping. The 100K T antigen was predominantly associated with the SV40 (I) DNA-containing complexes. The 17K T antigen, however, was not associated with the SV40 (I) or (RI) DNA-containing NP complexes. The functional significance of the SV40 100K T antigen in the SV40 (I) DNA-containing NP complexes was examined by immunoprecipitation of complexes from ts458-infected TC7 cells. The 100K T antigen was present in NP complexes extracted from cells grown at the permissive temperature but was clearly absent from complexes extracted from cells grown at the nonpermissive temperature and shifted up to the nonpermissive temperature for 1

hr before extraction, suggesting that the association of the 100K T antigen with the SV40 NP complexes is involved in the initiation of SV40 DNA synthesis. (43 refs)

- 79-1007 Relationship Between T-Antigen and Tumor-specific Transplantation Antigen in Simian Virus 40-transformed Cells.** (Eng) Chang, C. (NCI, NIH, Bethesda, MD, 20014); Martin, R. G.; Livingston, D. M.; Luborsky, S. W.; Hu, C. P.; Mora, P. T. *J Virol* 29(1): 69-75; 1979.

Simian virus 40 (SV40) tumor (T) antigen and tumor-specific transplantation antigen (TSTA) were partially purified from the nuclei of SV AL/N cells, an SV40-transformed mouse embryo fibroblast line, by precipitation with ammonium sulfate and chromatography on diethylaminoethyl- and DNA-cellulose and studied to clarify their relationship. T antigen was assayed by complement fixation and TSTA was assayed by its ability to immunize mice against SV40-containing ascites tumor cells. When T-antigen- and TSTA-containing preparations were sedimented through sucrose gradients, each antigen had a major peak of activity at 6.7S and minor peaks in other regions. Antiserum against T antigen (from tumor-bearing hamsters) immunoprecipitated TSTA activity. A preparation of T antigen from SV80 cells (an SV40-transformed human fibroblast line), which exhibited only one protein band after sodium dodecyl sulfate-polyacrylamide gel electrophoresis, had TSTA activity when as little as 0.6 µg of protein per mouse was used for immunization. These experiments demonstrate that T antigen, the product of the SV40 early A gene, is capable of inducing specific immunity against transplantation of SV40-transformed tumor cells in mice. (47 refs)

- 79-1008 Fibronectin Expression is Determined by the Genotype of the Transformed Parental Cell in Heterokaryons Between Normal and Transformed Fibroblasts.** (Eng) Laurila, P. (Dept. Pathology, Univ. Helsinki, Helsinki, Finland); Wartiovaara, J.; Stenman, S. *J Cell Biol* 80(1): 118-127; 1979.

The expression of fibronectin (FN), a cell-surface-associated transformation-sensitive glycoprotein, was studied in hetero- and homokaryons of normal and simian virus 40 (SV40)-transformed human fibroblasts (FB). FN was stained with rabbit antiserum against human plasma FN and fluorescein isothiocyanate-conjugated sheep anti-rabbit IgG. Cells were identified under the phase-contrast microscope according to the number of nuclei and degree of cytoplasmic labeling with polystyrene particles. The phenotype of the identified cell was then determined from the distribution and intensity of the FN fluorescence. The fluorescence of surface-associated and intracellular FN was evaluated separately. Normal FB homokaryons had an intense surface-associated and intracellular FN fluorescence similar to that of

unfused cells. Transformed cells and their homokaryons had a minimal surface-associated and a weak intracellular FN fluorescence. In heterokaryons formed between transformed and normal FB, the expression of surface-associated FN fell within 24 hr to the level in transformed cell homokaryons. The change was detectable at 3 hr after fusion and was gene dose-dependent. Intracellular FN expression in the heterokaryons was little affected, compared with that in normal FB homokaryons. The results indicate that the transformed genome determines FN expression in heterokaryons. Whether this is exclusively a result of the dominance of the transformed state or whether it is affected by the state of differentiation of the parental cells is not known. (50 refs)

- 79-1009 Circular, Circular-Linear and Branched Herpes Simplex Virus DNA Molecules from Arginine Deprived Cells.** (Eng) Becker, Y. (Lab. Molecular Virology, Hadassah Medical Sch., Hebrew Univ., Jerusalem, Israel); Asher, Y.; Friedmann, A.; Kessler, E. *J Gen Virol* 41(part 3): 629-633; 1978.

The structure of herpes virus DNA synthesized in arginine-deprived BSC-1 cells infected with the HF strain of herpes simplex virus (HSV) was studied. About 90% of the HSV DNA molecules from arginine-deprived cells had a linear conformation with an av length of 52 µm. The contour lengths of the repeat sequences, long component, and short component were 2.5, 37, and 5.2 µm, respectively. About 1.7% of the linear DNA molecules had the conformation of replicative intermediates of HSV DNA. Two types of circular DNA were noted: one type with a contour length corresponding to a complete genome, and one type with a contour length smaller than genome size. Two new species of HSV DNA were observed: a linear DNA with short and long branches and a contour length of 52 µm; and a circular-linear component of the circular-linear species varied from 4.4 to 32.2 µm, and the circular component ranged from 2.7 to 12.1 µm. In some cases the linear component was 3 to 5 times the contour length of the circular component. (14 refs)

- 79-1010 Isolation of a Nucleocapsid Polypeptide of Herpes Simplex Virus Types 1 and 2 Possessing Immunologically Type-Specific and Cross-Reactive Determinants.** (Eng) Heilman, C. J. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Zweig, M.; Stephenson, J. R.; Hampar, B. *J Virol* 29(1): 34-42; 1979.

The approx 40,000-mol wt polypeptides (p40's) from herpes simplex virus types 1 and 2 (HSV-1 and HSV-2, respectively) were purified by gel filtration and ion exchange chromatography and compared using direct and competition radioimmunoassays. The p40's of HSV-1 and HSV-2 were shown to possess cross-reactive and type-specific determinants. Both determinants apparently resided on the same polypeptide

molecule. Intratypic differences were not detected in the antigenic specificities of the p40's from the different strains of HSV-1 and HSV-2 studied. Antigens produced in pseudorabies virus-infected cells did not exhibit detectable cross-reactivity with the p40's of HSV-1 or HSV-2. The observed cross-reactivity between HSV-1 and HSV-2 p40's and antigens produced in cells productively infected with simian herpesvirus SA8 suggested that SA8 virus and HSV share cross-reactive antigenic determinants. Preliminary studies with human sera indicated that the p40 immunoassay should allow for the accurate determination of antibody levels to HSV-1 and HSV-2 type-specific and cross-reactive antigens in human sera. 79-1011 Enhanced Plating Efficiency of Herpes Virus DNA on Herpes Simplex Virus Type 1 DNA-transformed Cells. (Eng) Colbere-Garapin, F. (Unite de Virologie Medicinale, Institut Pasteur, 75724 Paris Cedex 15, France); Horodniceanu, F. *J Natl Cancer Inst* 62(1): 129-131; 1979.

Hamster cells transformed by sheared herpes simplex virus (HSV) DNA (EH/A44), control cells resulting from the spontaneous transformation of the same primary cell culture (EHT), baby hamster kidney cells transformed by polyoma virus (BHK-21/Py), and hamster cells transformed by human cytomegalovirus (Cx90/3B) were transfected with varying amounts of purified HSV type 1 (HSV-1) DNA, and the efficiency of plating of the HSV-1 DNA was determined. Below 0.0037 μ g of input DNA, the dose-response curves were linear, and the plating efficiency in EH/A44 cells was > 15 times that in EHT and BHK-21/Py cells and 100 times that in Cx90 cells. When the infectivity of HSV-1, HSV-2, and *Herpes eidolon* DNA's tested by transfection in various normal and spontaneously transformed, HSV-transformed, and other virus-transformed cell lines, these DNA's generally plated more efficiently on HSV-transformed cells than did intact virus. Furthermore, HSV-1 and HSV-2 DNA plated more efficiently on HSV-1 DNA-transformed (EH/A44) cells than on control cell types, in contrast to *H. eidolon* DNA. Therefore, it appears that the partial resistance of EH/A44 cells to superinfection by intact HSV can be overcome by transfection with viral DNA's. The high competence of EH/A44 cells for transfection with HSV DNA supports the concept that early events (ie, adsorption, penetration, and uncoating) are involved in the reduced plating efficiency of whole virus on HSV-transformed cells. 79-1012 Reversible Inhibition of the Induction of DNA Polymerase of Herpes Simplex Virus Type 2 in HeLa Cells. (Eng) Nishigori, H. (Dept. Molecular Medicine, Mayo Clinic, Rochester, MN, 55901); Sato, M.; Nishimura, C. *Arch Virol* 58(4): 335-340; 1978.

The effects of 2-mercapto-1-(β -4-pyridylethyl)benzimidazole (MPB) on the induction of herpes simplex virus type 2

(HSV-2)-specific DNA polymerase were studied in HeLa cells. The cells were infected with HSV-2 in the presence of different concentrations of MPB (0, 50, or 75 μ g/ml) for 24 hr, and the DNA polymerase activities were determined. The activity in infected cell lysates was almost completely absent in cells treated with MPB, which indicates that enzyme induction was inhibited, since MPB does not directly inhibit viral DNA polymerase. The MPB must be added within 3 hr after infection to block enzyme induction completely. In HeLa cells infected with HSV-2 in the presence of MPB for 9 hr, washed with medium, and refed with fresh medium, viral DNA polymerase began to appear after 6 hr in new medium. This recovery was prevented by the addition of cycloheximide (100 μ g/ml) or of a low concentration of actinomycin D (0.05 μ g/ml). These results suggest that the appearance of DNA polymerase activity after removal of MPB requires the de novo synthesis of protein and the participation of nucleoli. Although the mechanism of action of MPB remains unknown, it may block the induction of HSV-2 DNA polymerase through its effect on nucleolar function. (16 refs)

79-1013 Persistence of Herpes Simplex Virus Type 1 in Rat Neurotumor Cells. (Eng) Doller, E. (Roche Inst. Molecular Biology, Nutley, NJ, 07110); Aucker, J.; Weissbach, A. *J Virol* 29(1): 43-50; 1979.

A chemically induced rat CNS glioma cell line (C143) was infected with herpes simplex virus type 1 (HSV-1), and the preparation and properties of three lines derived from these cells are described. HSV-1 infection line C143 led to almost complete destruction of the cells. Cells that survived the infection were isolated and shown to produce infectious HSV particles for variable lengths of time in culture ranging from 20 to 57 passages. Even though infectious virus production eventually ceased, the cell lines continued to produce herpes-specified proteins, as measured by immunological techniques. These cells also showed herpesviruslike structures in the electron microscope. The persistently infected cells that produced HSV antigens and bore HSV sequences were resistant to superinfection by HSV-1. The resistance was not due to failure of adsorption of the virus or to the production of interferon by the cells. The nature of the block in HSV replication in these neurotumor cells, which contain and partially express the HSV genome, is unknown, but it may offer an interesting parallel to the known latency of HSV in neural tissues. (22 refs)

79-1014 Relationship of Herpes Simplex Virus Type-2 Antibodies and Squamous Dysplasia to Cervical Carcinoma In Situ. (Eng) Thomas, D. B. (Program Epidemiology and Biostatistics, Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA, 98104); Rawls, W. E. *Cancer* 42(6): 2716-2725; 1978.

This study was made to investigate further whether herpes simplex virus type 2 (HSV-2) plays a role in the etiology of

cervical neoplasia and to provide additional information regarding the possible etiologic relationship between carcinoma in situ (CIS) and dysplasia. Serum specimens from 75 women with cervical CIS, 84 with squamous dysplasia, and 132 controls who had been interviewed previously and tested for complement-fixing antibodies against a number of organisms were analyzed for HSV-2 antibodies. CIS and severe dysplasia were associated with HSV-2 antibodies. Mild dysplasia was related to evidence of prior infection by *Trichomonas vaginalis*, adenoviruses, and *Mycoplasma pneumoniae*, plus a history of vaginal discharge. Severe dysplasia was less strongly related to these variables. The relative risk of dysplasia increased with the number of different pathogens by which a woman had been infected. It is concluded that HSV-2 may be a cause of CIS, that much dysplasia is a nonspecific reaction of the cervical epithelium to chronic inflammation, and that dysplastic lesions that are caused by HSV-2 and, hence, may be precursors to CIS tend to be distinguished by their severity. The six related case-control studies in the literature have shown a positive association between the presence of HSV-2 antibodies and CIS. In these studies, the strength of the association increased with the severity of the lesion, additional evidence that only some of what is called dysplasia is caused by HSV-2. (30 refs)

- 79-1015 Characterization of an Epstein-Barr Virus-induced DNA Polymerase.** (Eng) Ooka, T. (Departement de Biologie Generale et Appliquee, Universite Claude Bernard-Lyon I, 69621 Villeurbanne, France); Lenoir, G.; Daillie, J. *J Virol* 29(1): 1-10; 1979.

The DNA polymerase induced after iododeoxyuridine (IUdR) treatment of Epstein-Barr virus (EBV) producer (P3HR-I) cells was partially purified, its biological properties were compared with those of cellular DNA polymerases, and its relationship to early antigen (EA) was examined. The addition of IUdR to P3HR-I cell cultures led to a large increase in both EBV-induced DNA polymerase activity and EA-positive cells. This EBV-induced DNA polymerase was separated from cellular α - and β -polymerases by sequential column chromatography on Sepharose 6B, diethylaminoethyl-cellulose, and phosphocellulose, resulting in about 320-fold partial purification. The partially purified enzyme could be distinguished from the cellular DNA polymerases by its activation with salts, its catalytic properties, and its sensitivity of N-ethylmaleimide, phosphonoacetic acid, 9- β -D-arabinofuranosyl-ATP (araATP), and 1- β -D-arabinofuranosylcytosine 5'-triphosphate (araCTP). The viral polymerase showed properties similar to those reported for other herpesvirus DNA polymerases. It exhibited optimal activity for copying activated calf DNA in the presence of 50 mM $(\text{NH}_4)_2\text{SO}_4$ and was resistant to 150 mM $(\text{NH}_4)_2\text{SO}_4$. It utilized with high efficiency template-primer poly(dC)-oligo(dG)₁₂₋₁₈ or poly(dA)-oligo(dT)₁₂₋₁₈, but it failed to copy poly(rA)-oligo(dT)₁₀ and oligo(dT)₁₀, indicating that this enzyme has properties distinct from those of DNA polymerase γ , reverse transcriptase, and terminal deoxynu-

cleotidyl transferase. Phosphonoacetic acid inhibited not only EBV DNA polymerase, but also, to a lesser degree, cellular DNA polymerase α . AraATP did not markedly inhibit viral enzyme activity, but polymerase α was inhibited completely. Both EBV polymerase and polymerase α were inhibited to a similar degree by araCTP. (31 refs)

- 79-1016 Cultured "Hairy Cells" Infected with Epstein-Barr Virus: Evidence for B-Lymphocyte Origin.** (Eng) Lemon, S. M. (Univ. North Carolina Sch. Medicine, Chapel Hill, NC); Pagano, J. S.; Utsinger, P. D.; Sinkovics, J. G. *Ann Intern Med* 90(1): 54-55; 1979.

The origin of a "hairy cell" line (line 4972) established from the spleen of a 30-yr-old black man with leukemic reticuloendotheliosis was studied. Eighty-five percent of the cells contained Epstein-Barr virus (EBV) nuclear antigen and 11% were positive for EBV capsid antigen. The presence of EBV DNA in the cells was confirmed by RNA-DNA hybridization and DNA-DNA renaturation kinetics. The latter technique also demonstrated a 95% homology between the EBV DNA extracted from the hairy cell line and the EBV DNA derived from the P3HR-I African Burkitt's lymphoma cell line. Although evidence suggests a causative role for EBV in African Burkitt's lymphoma, etiologic significance cannot be assigned to the virus found in the hairy cell. No EBV DNA could be detected in three leukemic reticuloendotheliosis tumor specimens, including the spleen from which line 4972 was established. Virus capable of transforming human umbilical cord lymphocytes could not be recovered from the hairy cells. Infection with EBV is a characteristic that hairy cells may share with normal B lymphocytes and is indicative that these cells may be, at least in some situations, of B-lymphocyte origin. (5 refs)

- 79-1017 Epstein-Barr Virus Antibodies in Sudanese Patients with Nasopharyngeal Carcinoma: A Preliminary Report.** (Eng) Malik, M. O. (Pathology Dept., Faculty Medicine, Riyadh Univ., P.O. Box 2925, Riyadh, Saudi Arabia); Banatvala, J.; Hutt, M. S.; Abu-Sin, A. Y.; Hidaytallah, A.; El-Hadi, A. E. *J Natl Cancer Inst* 62(2): 221-224; 1979.

Epstein-Barr viral capsid antigen antibody titers were determined in the sera of 208 Sudanese cancer patients and 18 normal controls by an indirect immunofluorescence technique. Of the patients, 41 had anaplastic nasopharyngeal carcinoma (NPC), 77 had other cancers of the head and neck, 21 had leukemia or malignant lymphoma, 6 had specific granulomas, and 63 had cancers at all other sites. All NPC patients had anti-Epstein-Barr virus (EBV) titers >40 ; 87.9% had titers ≥ 320 and 43.9% had titers $\geq 2,560$. The geometric mean titer (GMT) level of these patients was 1,855. These high titers were independent of age, sex, locality, or tribe. All leukemia and lymphoma patients also had titers $>$

40, although only 33.3% were ≥ 320 and 4.8% $\geq 2,560$. All the remaining groups had significantly more subjects with titers < 40 , fewer with titers ≥ 320 , and very few with titers of $\geq 2,560$. Their GMT was 4-16 times lower than that of NPC patients. These findings lend further support to the hypothesis that NPC and EBV are associated. (23 refs)

79-1018 Cell-Density-Dependence for Growth in Agarose of Two Human Lymphoma Lines and its Decrease after Epstein-Barr Virus Conversion. (Eng) Montagnier, L. (Unite d'Oncologie Virale, Departement de Virologie, Institut Pasteur, Paris, France); Gruest, J. *Int J Cancer* 23(1): 71-75; 1979.

Two Epstein-Barr virus (EBV)-negative Burkitt's lymphoma lines (BJAB and Ramos) and their EBV-converted derivatives were compared with respect to growth in agarose medium. BJAB cells at low concentrations did not grow in agarose, but an abrupt rise in cloning efficiency was observed with concentrations of 3 to 6 $\times 10^5$. BJAB cells converted by the B95/8 or P3HR1 strain of EBV could form colonies at concentrations as low as 5 $\times 10^4$. The max cloning efficiency was higher with the EBV-converted lines. In liquid medium, BJAB cells grew only slightly more slowly than their converted derivatives. The cloning efficiency of both cell types was greatest when pyrolyzed water was used in the agarose, when the agarose concentration was 0.4% in the underlayer and 0.285% in the overlayer, in the presence of 10% fetal calf serum, and in the presence of feeder MRC5 conditioning cells. Similar but even more striking results were obtained when the Ramos line was compared with its EBV-converted derivatives. The difference may be related to a super-transformation state induced by EBV in the converted derivatives. (16 refs)

79-1019 Gibbon Ape Leukemia Virus-Hall's Island: New Strain of Gibbon Ape Leukemia Virus. (Eng) Reitz, M. S. (Lab. Tumor Cell Biology, NCI, NIH, Bethesda, MD, 20014); Wong-Staal, F.; Haseltine, W. A.; Kleid, D. G.; Trainor, C. D.; Gallagher, R. E.; Gallo, R. C. *J Virol* 29(1): 395-400; 1979.

A C-type virus, gibbon ape leukemia virus-Hall's Island (GaLV-H), was isolated from a gibbon ape with acute lymphocytic leukemia from a small colony on Hall's Island near Bermuda. It was compared with simian sarcoma virus (SiSV) and other GaLV isolates (GaLV-SF, GaLV-SEATO, and GaLV-Br) by p30 and reverse transcriptase serology and analyses of nucleic acid sequences. Nucleic acid hybridization experiments indicated that GaLV-H was about 60% related to the other GaLV isolates, but only about 20% related to SiSV. RNase T1 oligonucleotide fingerprint analysis suggested that, of the previously described infectious C-type viruses of primates, GaLV-H is most closely related to GaLV-Br. Thus, GaLV-H represents a fifth distinct strain of the infec-

tious primate C-type viruses. It is possible that a substantial portion of the observed difference in hybridization between the RNA of GaLV-H and those of the other isolates was due to differences in RNA sequences coding for the envelope protein (gp70). (26 refs)

79-1020 Hepatitis B Virus Infection and Chronic Liver Disease in Taiwan. (Eng) Chen, D. S. (Dept. Internal Medicine, Natl. Taiwan Univ. Hosp., Taipei, Taiwan 100); Sung, J. L. *Acta Hepatogastroenterol (Stuttg)* 25(6): 423-430; 1978.

The presence of hepatitis B surface antigen (HBsAg) and antibody to HBsAg (anti-HBs) in 385 patients, most of whom had chronic liver diseases (127 with hepatomas), and 729 healthy adults was determined by reversed passive hemagglutination and passive hemagglutination, respectively. Approx 15% of the healthy adults were HBsAg-positive and 45% were anti-HBs positive, indicating that hepatitis B virus (HBV) infection had occurred in almost two-thirds of the healthy population before adulthood. The prevalences of HBsAg were $> 80\%$ in chronic hepatitis, cirrhosis, and hepatoma, indicating an intimate relationship of these diseases to HBV. On the other hand, the positive rates of anti-HBs in these diseases were far lower than those in healthy people and in patients with other diseases, a situation similar to that in chronic HBsAg carriers. The prevalence of HBsAg in the hepatoma patients was unusually high (82.7%), in contrast to that in patients with other malignancies (11.9%). Hepatoma patients both with and without cirrhosis were found to have a high prevalence of HBsAg, indicating that there is an even more intimate relationship between hepatoma and HBV. (58 refs)

79-1021 Adenovirus Infection and Cytopathic Alterations of Human Cervical Epithelial Cells In Vitro. (Eng) Vesterinen, E. (Cancer Res. Center, Univ. North Carolina, Chapel Hill, NC, 27517); Vaheri, A.; Paavonen, J.; Saksela, E. *Acta Cytol (Baltimore)* 22(6): 566-569; 1978.

To analyze the adenovirus-induced cervical infection in detail, monolayer cultures of human ecto- and endocervical epithelial cells were used as targets for adenovirus infection in vitro. In both types of cultures, adenovirus type 1 resulted in a slowly progressing lytic infection with persistent production of infectious virus, viral antigens, and cytopathic alterations in a fraction of cells. In both cell types, the first morphological alterations were observed 48 hr after inoculation of the cultures with about 1 plaque-forming U/cell. The changes were similar in both cell types. Although many alterations may represent unspecific lesions, nuclear changes consisting of lobulated inclusion bodies seemed to be characteristic. The inclusions were mainly irregular and somewhat diffuse, but as the destruction of the explant colonies spread, more regular large inclusions were seen. The cytoplasm of

adenovirus-altered cells was morphologically normal, but vacuolization could sometimes be seen during the latest phases of the infective cycle. In cultures of ectocervical cells studied during the second week after infection, 5%-10% of the cells were positive in immunofluorescence. In endocervical cultures, a somewhat weaker adenovirus-specific immunofluorescence was seen in about 1% of cells. The alterations produced by adenovirus infection differ from those observed during herpes virus infections, and they may serve as indicators of cervical adenovirus infection in cytologic screening. (16 refs)

- 79-1022 Coincidence of the Promoter and Capped 5' Terminus of RNA from the Adenovirus 2 Major Late Transcription Unit.** (Eng) Ziff, E. B. (Rockefeller Univ., New York, NY, 10021); Evans, R. M. *Cell* 15(4): 1463-1475; 1978.

The map positions and structures of the late promoter and capped 5' terminus of late nuclear and cytoplasmic RNA from the major late transcription unit of adenovirus 2 (Ad2) were analyzed. The data showed that the Ad2 major late promoter and the template for the 5' terminus of capped late transcripts map at the same coordinate within Ad2 DNA. The late promoter was mapped at coordinate 16.5 ± 0.5 by applying the method of nascent chain analysis to short in vivo pulse-labeled nuclear RNA. Polyadenylation and cap formation, two events in messenger RNA (mRNA) synthesis, occurred on unspliced molecules. A nine residue complementarity was shown between the first leader segment and the 3' terminus of 18S rRNA, suggesting that the first leader functions in ribosome binding. Nucleotide sequences from the promoter region were compared with cellular counterparts. Strong homologies at cap sites and splice points suggested that the virus and cell shared closely related mechanisms for mRNA 5' end synthesis and splicing. (31 refs)

- 79-1023 Steps in the Processing of Ad2 mRNA: Poly(A)+ Nuclear Sequences are Conserved and Poly(A) Addition Precedes Splicing.** (Eng) Nevins, J. R. (Rockefeller Univ., New York, NY, 10021); Darnell, J. E. *Cell* 15(4): 1477-1493; 1978.

The order of the steps in the formation of late adenovirus 2 (Ad2) messenger RNA's (mRNA's) was studied. The data indicate that late in Ad2 infection, a series of at least 13 mRNA's arranged in five 3' coterminal groups is derived from the 16-99 transcriptional unit. The posttranscriptional processing involves addition of cap, endonucleolytic cleavage, poly(A) addition, and RNA:RNA splicing. About 20% of the RNA transcribed from each of the five regions containing the 3' mRNA termini is conserved, and all, or most, of the poly(A)-terminated nuclear RNA is conserved. Thus, only one mRNA is made from each transcriptional event in the 16-99 region. Two tentative rules of transcriptional unit de-

sign and mRNA processing were postulated: the RNA polymerase continues past all poly(A) sites in a transcription event; and the first step in processing a primary transcript is cleavage and poly(A) addition. For those transcriptional units containing more than one poly(A) site, the choice of poly(A) would determine the group of mRNA's within which the final choice of mRNA is made. For those transcriptional units containing only one poly(A) site, the addition of poly(A) may be a necessary first step in processing, but the choice of mRNA is made at the splicing step. (64 refs)

- 79-1024 Nucleotide Sequence at the Junction Between the Coding Region of the Adenovirus 2 Hexon Messenger RNA and Its Leader Sequence.** (Eng) Akusjarvi, G. (Inst. Microbiology, Biomedical Center, Box 581, S-751 23 Uppsala, Sweden); Pettersson, U. *Proc Natl Acad Sci USA* 75(12): 5822-5826; 1978.

The nucleotide sequence at the amino terminal end of the gene for the adenovirus type 2 (Ad2) hexon is described, along with its relation to the leader sequence of the hexon messenger RNA (mRNA). For most experiments, an approx 600-nucleotide fragment located between map positions 50.1 and 51.1 was isolated and further cleaved with endonucleases before being end-labeled with polynucleotide kinase. In each case, the labeled fragments were recleaved with *Hae* III to generate fragments labeled at only one end. To determine the sequence immediately leftward of the cleavage site for *Sma* I at position 51.1, end-labeled fragment *Sma* I-D was recleaved with *Bgl* II. The established 139-base pair DNA sequence included an AUG initiator codon located 75-77 nucleotides to the left of the *Sma* I cleavage site and codons for the first 26 amino acids of the hexon polypeptide. Using the purified hexon mRNA as template and separated strands of small restriction enzyme fragments as specific primers, it was possible to copy the complete 5' noncoding region of the hexon mRNA with reverse transcriptase and determine part of its sequence. The region was estimated to be 235 nucleotides long by gel electrophoresis, with the tripartite leader sequence beginning 39 nucleotides to the left of the initiator codon. The DNA sequence at the junction of the leader sequence permitted the formation of secondary structures that may be important for splicing reactions, serving as recognition signals for splicing enzymes. (24 refs)

- 79-1025 Analysis of Human Cancer DNA for DNA Sequences of Human Adenovirus Type 4.** (Eng) Mackey, J. K. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, 3681 Park Ave., St. Louis, MO, 63110); Green, M.; Wold, W. S.; Rigden, P. *J Natl Cancer Inst* 62(1): 23-26; 1979.

Samples of human tumor DNA were assayed for adenovirus type 4 (Ad4) DNA sequences by molecular hybridization with in vitro-labeled Ad4 DNA (specific activity = approx

10^7 ^3H cpm/ μg). Hybridizations of 500 cpm Ad4 DNA (0.05 nanograms) and 6 mg tumor DNA/ml (0.3 mg) were carried out in liquid phase. No viral DNA sequences were detected in 31 squamous cell carcinomas of the lung, 5 adenocarcinomas of the lung, 4 oat cell carcinomas of the lung, 4 carcinomas of the stomach, 10 carcinomas of the colon, 3 carcinomas of the kidney, 3 carcinomas of the breast, 2 carcinomas of the ovary, and 6 Hodgkin's lymphomas. Reconstruction experiments (using unlabeled Ad4 DNA added to 6 mg calf thymus DNA/ml) performed under the same conditions as the tumor analyses indicated that the probe detected Ad4 sequences ranging from one copy of approx 5% of the Ad4 genome per cell to one copy of the entire Ad4 genome per every 10th or 20th cell. These results suggest (but do not prove) that none of these tumors were induced by Ad4 and, consequently, that Ad4 presents no carcinogenic risk in human cancers. (30 refs)

79-1026 Adenovirus Type 12 Gene 401 Function and Maintenance of Transformation. (Eng) Ledin-ko, N. (Dept. Biology, Univ. Akron, Akron, OH, 44325); Schaeufele, J.; Soorma, O. *J Virol* 29(1): 250-260; 1979.

Rat (3Y1) and hamster embryo brain cells transformed by wild-type adenovirus type 12 or the DNA-minus temperature-sensitive mutant $\Delta 401$ were characterized at the permissive and nonpermissive temperatures with respect to expression of parameters of the transformed phenotype. The $\Delta 401$ -transformed 3Y1 cells, but not the wild-type transformants, displayed a temperature-sensitive response with respect to morphology, saturation density, growth rate, cloning in soft agar, colony formation on plastic at low cell densities in 1% serum medium, and expression of tumor (T) antigen(s). In temperature shiftdown experiments, the density-dependent inhibition of growth of the $\Delta 401$ -transformed cells was found to be reversible, as was, to some extent, the low efficiency of colony formation at low cell densities in 1% serum. Examination of hamster transformants for their ability to clone in soft agar at permissive and nonpermissive temperatures showed that this property was temperature-dependent, again only in the $\Delta 401$ transformants and not in the wild-type transformants. Alteration in uptake of 2-deoxyglucose or in intracellular cyclic AMP content was not a characteristic of the adenovirus-transformed phenotype in the 3Y1 cells. The findings suggest that an active 401 function is required for maintenance of the adenovirus-transformed cell phenotype. (39 refs)

79-1027 Comparative Study by Immunofluorescence of T and P Antigens Induced by Adenovirus Type 12 in Permissive and Nonpermissive Cells. (Eng) Ribeiro, G. (Unit Virology, Biological Res. Center, Gulbenkian Inst. Science, Oeiras, Portugal); Vasconcelos-Costa, J. *Arch Virol* 58(4): 269-276; 1978.

The development of adenovirus type 12 (Ad12) tumor (T) antigen and of the complex of antigenic early proteins designated as P antigen was studied by immunofluorescence in productively infected human KB cells and abortively infected rabbit kidney (RK-13) cells. The cells were infected with Ad12 at a multiplicity of infection of 2×10^{-2} TCID₅₀/cell. T antigen was detected in both cell types as early as 6 hr after infection. In KB cells, it appeared both as small dots and as short, very thin nuclear flecks and reached a max (>90% of cells being positive) at 18 hr after infection. At the time of max abundance in RK-13 cells, also 18 hr after infection, T antigen formed a net of long, intertwined filaments that completely filled the nuclei. By 24 hr after infection, part of the filaments condensed into a large aggregate that finally was apparently degraded at about 72 hr. T antigen was never observed in the cytoplasm. P antigen was first detected in KB cells 9 hr after infection; up to 18 hr after infection, it was very similar in form to T antigen. By 24 hr after infection, when almost every cell was positive, the nuclei showed one or two large fluorescent bodies comprised of rings or clusters of large balls. P antigen was first detected in RK-13 cells 12 hr after infection and resembled T antigen in KB cells. The later component of P antigen in KB cells is probably a DNA-DNA-binding protein replication complex that is dependent on newly synthesized viral DNA. (23 refs)

79-1028 Identification of Murine Endogenous Xenotropic Retrovirus in Cultured Multicellular Tumour Spheroids from Nude-Mouse-Passaged Nasopharyngeal Carcinoma. (Eng) Crawford, D. H. (Dept. Pathology, Medical Sch., Univ. Bristol, Univ. Walk, Bristol BS8 1TD, England); Achong, B. G.; Teich, N. M.; Finerty, S.; Thompson, J. L.; Epstein, M. A.; Giovanella, B. C. *Int J Cancer* 23(1): 1-7; 1979.

Culturing nude mouse-passaged nasopharyngeal carcinoma (NPC) epithelial cells as multicellular spheroids allowed the definitive identification of endogenous xenotropic retrovirus. Cultured tumor fragments and free cells grown in agar plates formed multicellular tumor spheroids, 40-500 μm in diameter, after 10-14 days. The spheroids continued to grow in size, increased in number by budding, and could be subcultured for up to 6 mo. Histological examination of the spheroids demonstrated a compact outer shell of actively growing epithelial cells surrounding an inner core of loosely packed cells, some of which were degenerating and had pyknotic nuclei. Ultrastructural examination showed large numbers of typical immature C-type virus particles in cytoplasmic spaces and between the cells within the spheroids. After bromodeoxyuridine treatment, the spheroids generally contained even more numerous C-type particles. Experiments in which tumor spheroids were cocultivated with monolayer cell lines suggested that the virus produced by the cells in the NPC spheroids infected the monolayer cells, and thus had properties in common with xenotropic murine type-C virus. Further experiments suggested that the origin of the type-C virus was

the nude mouse host through which the NPC tumor cells had passed. (21 refs)

- 79-1029 Antigen Associated with Oncornavirus D in Continuous Cultures of Human and Animal Cells.** (Rus) Posevaia, T. A. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Kosiakova, N. P.; Tsareva, A. A.; Novokhatskii, A. S. *Vopr Virusol* (6): 714-717; 1978.

A series of continuous and primary trypsinized cultures of human and animal cells were analyzed for the presence of a new antigen associated with oncornavirus D. Specific sera against new antigen reacted with antigens isolated from HeLa, V, KB, VERO, and CV-1 cells, but showed no reaction with FS-4, L-929 and SIRC cells. Antigen was also present in HEPv-2 and J-96 cells. The new antigen could not be detected in cultures infected with oncogenic viruses other than oncornavirus D. (16 refs)

- 79-1030 Comparative Study of Proteins of Oncornaviruses A and D in Continuous Culture of Human Cells J-96 by Isoelectric Focusing and Electrophoresis in Polyacrylamide Gel.** (Rus) Kitsak, V. Ia. (Central Inst. Advanced Training Physicians, Moscow, USSR); Moisiadi, S. A.; Delimbetova, G. A.; Dotsenko, V. L.; Krispin, T. I. *Vopr Virusol* (6): 718-722; 1978.

Isoelectrofocusing and polyacrylamide gel electrophoresis were employed for analysis of the proteins from intracellular

virion type A and extracellular virion type D produced by human lymphoblastoid J-96 cells. It was found that the proteins of virion type D were localized in zones with pH of 3.7, 4.0, 4.4, 4.7, 5.6, 6.5, 8.1, 9.45 and 10.0, compared with 4.0, 4.9, 6.7, 7.3, 9.0, 9.45 and 10.0 for protein from virion type A. Type A virions did not contain proteins with mol wt of 10,000, 12,000, 15,000 or 27,000 daltons. These findings, which confirm previously reported data on the differences between A and D virions from HEP-2 cells, indicate that type A virions are not the precursors of type D virions. (9 refs)

- 79-1031** Correlated Expression of a B-Lymphocyte-specific Glycoprotein (gp27/35) and the EBV Receptor/C3 Receptor Complex in Sublines from the Same Burkitt Lymphoma. (Eng) Klein, G. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Hyman, R.; Trowbridge, I. *Int J Cancer* 23(1): 37-41; 1979.

The relationship between a B-lymphocyte-specific glycoprotein (gp27/35) and the Epstein-Barr virus (EBV) receptor/complement (C3) receptor complex was reexamined in virus-producer and nonproducer sublines derived from the Burkitt's lymphoma line Jijoye and its P3HR-1 clone. These sublines were previously found to differ in the expression of EBV receptors and, in parallel, C3 receptors. Quantitative absorption studies demonstrated a close parallelism between the expression of the EBV receptor-complement receptor complex and the glycoprotein. Both were expressed on the cell line from which the cytopathic-virus-producing P3H3 line is derived. However, both were greatly reduced in the P3H3 line itself and in several other sublines derived from P3H3 cells. Both gp27/35 and EBV-complement receptors reappeared in parallel in the "revertant" P3HR-1 NP line and, more strongly, in line BU-P3HR-1. The results favor a relationship between gp27/35 and EBV/C3 receptor expression. (15 refs)

- 79-1032** *Helix pomatia* A Hemagglutinin: Selectivity of Binding to Lymphocyte Surface Glycoproteins on T Cells and Certain B Cells. (Eng) Axelsson, B. (Dept. Immunology, Univ. Stockholm, S-10691 Stockholm, Sweden); Kimura, A.; Hammarstrom, S.; Wigzell, H.; Nilsson, K.; Mellstedt, H. *Eur J Immunol* 8(11): 757-764; 1978.

The surface structures of human and mouse lymphocytes responsible for binding to *Helix pomatia* A hemagglutinin (HP) were studied. Lymphocytes were surface-labeled by lactoperoxidase-catalyzed iodination, or by galactose oxidase oxidation followed by reduction with tritiated sodium borohydride. The labeled cells were then lysed with detergent. Proteins binding to HP were isolated by affinity chromatography on HP-Sepharose and analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and autoradiography. A major cell-surface glycoprotein [gp: mol wt 150,000 (150K)] using reducing conditions on human lymphocytes was responsible for >90% of all HP binding. It was present on normal and malignant thymus-derived lymphocytes, on chronic lymphocytic leukemia cells, and on cells of a null cell leukemia line, an unidentified leukemia line, a lymphoblastoid cell line of B origin, and a stem cell lymphoma line. It was absent from lines of more differentiated

B cells (4 Burkitt's and non-Burkitt's lymphoma lines, 1 myeloma line) and from a histiocytic leukemia line. However, two of the four B lymphoma lines and the myeloma line displayed a 200K HP-binding surface gp. Biosynthetic labeling indicated that the 150K gp was synthesized by the lymphocytes. The results from surface- and biosynthetic-labeling established that the 150K protein is a sialylated gp. Mouse T cells (normal and malignant) but not normal adult B cells expressed a 130K HP-binding surface gp. The 150K HP-binding surface gp on the human cells may be considered a differentiation marker. - 79-1033** Recovery from Postoperative Immunosuppression: Efficacy of an Immunorestorative Drug. (Eng) Lundy, J. (Dept. Surgery, Univ. Connecticut Health Center, Farmington, CT); Lovett, E. J.; Conran, P. B. *Surg Forum* 29: 3-5; 1978.

Thiabendazole restored and impaired cell-mediated immunity of thiopental-, thiopental-halothane-, and thiopental-halothane- + surgically treated (hind limb amputation) C57BL/6 female mice; ie, it resulted in the recovery of normal mixed lymphocyte culture kinetics. (2 refs)

- 79-1034** Humoral and Cell-mediated Immune Competence of High-Cancer-Risk Canine Breeds. (Eng) Dorn, C. R. (Dept. Veterinary Preventive Medicine, Coll. Veterinary Medicine, Ohio State Univ., Columbus, OH, 43210); Heuschele, W. P. *Am J Vet Res* 39(12): 1932-1935; 1978.

The possibility that dogs with a high cancer risk (ie, boxers and terriers) might have breed-associated immune response anomalies was examined. Immune competence of four boxers and four terriers was compared with that of four beagles, which do not have a high cancer risk. There was no difference between the breeds in their humoral immune competence, as measured by hemagglutinating antibody response to sheep RBC, lymphocytotoxic antibody response following allogeneic skin grafting, and antibody activity following the injection of bacteriophage ϕ X-174. All dogs developed a hemagglutinin titer of 1:128 or greater by day 14, except for one boxer dog. The phage was cleared from the peripheral blood by the fourth day in all beagles, all terriers, and three boxers. In one boxer, the phage had cleared by the seventh day. Cytotoxic antibody against donor lymphocytes was detected in three beagles, three boxers, and four terriers. Following challenge exposure with purified protein derivative, all BCG-sensitized dogs developed a positive reaction of 10 mm or greater, the

reactions being as high as 16 mm. There was no consistent breed difference. Tritiated thymidine incorporation by phytohemagglutinin-purified-stimulated lymphocytes varied as greatly among dogs of one breed as it did between breeds. The mean stimulation indices for the three breeds were not significantly different. These indirect measurements of immune competence that may affect the development of neoplasms do not support either the hypothesis of immune surveillance or of immune enhancement. Temporal and other factors may have prevented the detection of an association between high-cancer-risk breeds and aberrant immune responses. (42 refs)

- 79-1035 Hybridization of T Lymphocytes: Characterization of a Suppressor Factor Produced by a Hybrid T Cell Line in Mice.** (Eng) Holliman, A. (Inst. Animal Physiology, Babraham, Cambridge CB2 4AT, England); Taussig, M. J. *J Physiol (Lond)* 284: 5P-6P; 1978.

The supernatant of a hybrid T-cell line produced by fusion of azaguanine-resistant thymoma BW5147 cells to spleen cells of mice immunized with sheep RBC (SRBC) suppressed the antibody response to SRBC in culture 80%-90%. The suppressive factor suppressed the response to SRBC more actively than that to other antigens and it could be absorbed specifically by SRBC. It is not an immunoglobulin, it carries determinants of the murine major histocompatibility gene complex, and it has two chains of mol wts 80,000 (80K)-90K and 20K-25K. (6 refs)

- 79-1036 Correlation Between Natural and Antibody-dependent Cell-mediated Cytotoxicity Against Tumor Targets in the Mouse. I. Distribution of the Reactivity.** (Eng) Santoni, A. (Istituto di Farmacologia, Università degli Studi di Perugia, 06100, Perugia, Italy); Herberman, R. B.; Holden, H. T. *J Natl Cancer Inst* 62(1): 109-116; 1979.

The expression of natural killer (NK) activity and levels of antibody-dependent cell-mediated cytotoxicity (ADCC) against RBL-5 TC mouse tumor cells (Rauscher murine leukemia virus-induced ascites cell line of C57BL/6 origin) coated with an alloantiserum were compared. NK activity and ADCC were tested simultaneously in an 18-hr ⁵¹Cr-release cytotoxicity assay (CRA), but characteristics of NK activity were the same when the CRA was performed for 4 hr. In normal spleens of individual mice, NK activity and ADCC levels fluctuated in a parallel manner. Activities were high in C3Hf, CBA, and several strains of nude mice, intermediate in BALB/c and C57BL/6 mice, and low in SJL mice. Peak activities for both functions occurred in 4- to 9-wk-old mice. Activity was highest in cells of the spleen and peritoneal cavity. Intermediate activities were found in lymph node and bone marrow cells, the lowest activities in thymus cells. Ip injection of lymphocytic choriomeningitis virus into several strains of mice caused a marked stimulation of both NK and

ADCC activities, whereas the presence of murine sarcoma virus-induced tumors depressed these activities. Although the two effector functions produced synergistic results against target cells sensitive to NK, cell susceptibility to NK activity was not a prerequisite for susceptibility to ADCC; target cells resistant to NK activity could be lysed when they were coated with alloantibody. The close correlation between NK cell and ADCC activity indicates that natural cell-mediated cytotoxicity is possibly due to the arming of K cells with natural antibodies. (59 refs)

- 79-1037 Monovalent Antibodies Directed to Transformation-sensitive Membrane Components Inhibit the Process of Viral Transformation.** (Eng) Lingwood, C. A. (Hosp. Sick Children, Toronto, ON M5G 1X8 Canada); Ng, A.; Hakomori, S. *Proc Natl Acad Sci USA* 75(12): 6049-6053; 1978.

The inhibition of the expression of the oncogenic phenotype by monovalent antibodies (Fab) directed to the transformation-sensitive cell-surface components galactoprotein a (Gap a) or gangliosides GM₁ or GM₂ is described. Mouse 3T3 cells infected with murine sarcoma virus were not transformed in terms of morphology or sugar uptake when they were cultured in the presence of Fab directed to GM₁ or Gap a. The inhibitory activity of these cell-surface ligands was not related to cell growth inhibition, because the Fab to globoside and divalent concanavalin A were growth inhibitory but not transformation inhibitory. Neither anti-GM₁ nor anti-Gap a Fab inhibited virus production. The inhibitory activity of anti-ganglioside and anti-Gap a Fab was also assessed in a normal rat kidney cell line transformed by a temperature-sensitive mutant of avian sarcoma virus (NRK/LA25). In this cell line, GM₁ (but not GM₂) and Gap a were transformation-sensitive cell-surface components. Expression of the transformed phenotype (changes in morphology, growth in 0.3% agar) at the permissive temperature was inhibited by preincubating the cells with anti-GM₁ or anti-Gap a Fab. GM₁ labeling of NRK/LA25 cells decreased at the permissive temperature, whereas preincubation of the cells with anti-Gap a, which induces inhibition of transformation after a temperature shift, prevented the decrease in GM₁ labeling. The data suggest a possible correlation between GM₁ and Gap a expression. Application of Fab to these transformation-sensitive components may prevent changes of these components on cell surfaces and thus may result in abortion of the phenotypic expression of transformation, even though the transforming gene (*src*) has been activated. These results indicate that pericellular structures influence gene expression. (44 refs)

- 79-1038 Immunopathogenicity and Oncogenicity of Murine Leukaemia Virus. IV. Antinuclear Antibody Response and Tumour Induction in B10.A Recombinant Mice.** (Eng) Croker, B. P. (Dept. Pathology, Box 3712, Duke Univ. Medical Center, Durham, NC, 27710); Bourdon,

M.; McConahey, P. J.; Dixon, F. J. *J Immunogenet* 5(6): 401-409; 1978.

Antinuclear antibody (ANA) production following murine leukemia virus (MuLV)-Scripps infection of B10.A and B10.A recombinant (2R, 3R, 4R, and 5R) mice was studied in an effort to identify the nuclear antigen(s) and the subregion of the *H-2* complex that might be involved in regulation of antibody type and titer. The mice could be divided into high- and low-responder groups. Compared with controls, however, all infected animals had significant increases in ANA titer and incidence. 3R and 5R mice had the highest incidence and titers up to 10 times those of the other groups, with the geometric mean titers of the females being significantly higher than those of the males. Most of the high ANA antibody was attributable to anti-histone antibody. A high response was associated with the H-2b haplotype and recombinant strains that were identical at the *I-A* subregion derived from H-2b parental stock. A low response was associated with the *I-A* subregion derived from the H-2k haplotype. Most infected mice of all groups had significantly elevated serum p30 and gp70 levels when tested by radioimmunoassay, and 72%-80% developed lymphomas. Elevated p30 levels were correlated directly with gp70 levels and inversely with tumor latency. Glomerulonephritis developed in 4%-28% of each infected group. No clear genetic basis could be established for glomerulonephritis incidence, serum p30 or gp70 levels, or latency of lymphoma development. (23 refs)

79-1039 Digestion of the Fifth Component of Complement by Leukocyte Enzymes: Sequential Generation of Chemotactic Activities for Leukocytes and for Tumor Cells. (Eng) Orr, F. W. (Dept. Pathology, Univ. Connecticut Health Center, Farmington, CT, 06032); Varani, J.; Kreutzer, D. L.; Senior, R. M.; Ward, P. A. *Am J Pathol* 94(1): 75-83; 1979.

The generation of chemotactic activity (CTA) for WBC and tumor cells by incubating the fifth component of complement (C5) with WBC enzymes was studied using the Walker carcinosarcoma (maintained as an ascites tumor), neutrophilic WBC from rabbits, and complement from normal human serum. The supernatant fluids from suspensions of human neutrophils that had ingested opsonized zymosan particles generated CTA for WBC and for tumor cells when incubated with C5. The generation of leukotactic activity (LTA) occurred 2-5 min after the onset of incubation. CTA for tumor cells appeared after 60 min, and its appearance was accompanied by a fall in LTA. LTA was also generated from the third component of complement (C3) after 2 min of similar treatment, but generation of CTA for tumor cells was not observed. The results of treating C5 with the purified lysosomal enzymes cathepsin G and elastase as well as with WBC granule extracts were similar. There was an initial generation of LTA that was followed by a decline in this activity and the generation of CTA for tumor cells. The generation of CTA's from C5 was blocked by prior treatment of WBC

preparations with Trasylol, a protease inhibitor. The interaction between C5 and WBC enzymes could occur readily in injured tissues or at sites of inflammatory responses, and it suggests a possible mechanism by which the development of metastatic lesions may be promoted at sites of tissue injury or inflammation. (24 refs)

79-1040 The Genetics of Teratocarcinoma Transplantation: Tumor Formation in Allogeneic Hosts by the Embryonal Carcinoma Cell Lines F9 and PCC3. (Eng) Avner, P. R. (Laboratoire d'Immunologie et Virologie des Tumeurs, Hopital Cochin, U152, Paris 75014, France); Dove, W. F.; Dubois, P.; Gaillard, J. A.; Guenet, J. L.; Jacob, F.; Jakob, H.; Shedlovsky, A. *Immunogenetics* 7(2): 103-115; 1978.

Two cultured lines of murine teratocarcinomas, F9 and PCC3, were grafted to a variety of allogeneic hosts, and the host strains were classified by their resistance or sensitivity to these carcinomas. Strains most sensitive to tumor induction by F9 were A/He, DBA/2, and SJL/J, each of which carries a histocompatibility (*H-2*) haplotype distinct from that of the syngeneic strain, 129. Strong *H-2* differences, therefore, are not sufficient to cause rejection of F9 tumors. Strain DBA/2 was sensitive to tumor production by PCC3, but A/He and SJL/J were completely resistant. The sensitivity of the rejection mechanism to sublethal x-irradiation and the transfer of resistance using lymphoid reconstitution of lethally irradiated animals indicate that the rejection of F9 and PCC3 has an immunological basis. Allograft rejection appears to be determined by a small number of loci. On the basis of F_1 and backcross analysis, resistance of B6 (an F9-resistant allogeneic strain) to F9 seems to be determined by a single recessive factor. B6 resistance to PCC3 seems to be determined by two or three independent loci. A/He resistance to PCC3 appears to be under the control of a single recessive factor linked to *H-2*. The fact that sensitive strains were readily found implies that the allograft rejection loci in mice are not highly polymorphic. Tumor resistance of strains C57BL/6 and AKR appears to result from the interaction of dominant or semidominant factors in the *H-2* region with other recessive elements in the genetic background. (26 refs)

79-1041 Facultative Phagocytosis by Leukemic B-Lymphocytes: Further Proof of the B-Cell Nature of Hairy Cells. (Eng) Catovsky, D. (M.R.C. Leukemia Unit, Royal Postgraduate Medical Sch., Du Cane Road, London W12 0HS, England); Sperandio, P.; O'Brien, M. In: *Recent Results Cancer Res* 64: 208-212; 1978.

In view of the suggestion that hairy cells may correspond to B lymphocytes with phagocytic properties, the phagocytic capacity of lymphocytes from patients with B-lymphoproliferative diseases other than hairy cell leukemia (leukemic reticuloendotheliosis) was studied. When incubated with

fresh human serum and latex particles approx 0.8 μ in diameter, approx 15% of the lymphocytes from three cases of prolymphocytic leukemia and nine cases of chronic lymphocytic leukemia were phagocytic. The phagocytosis was dependent upon the presence of serum. The predominant cell type (> 90%) in these samples was a leukemic lymphocyte with surface immunoglobulin and/or the ability to bind mouse RBC. In most cases, light and electron microscopy usually identified one or two ingested latex particles per cell, but in two cases 17%-30% of the lymphocytes had ingested three or more particles. The degree of phagocytosis correlated significantly with the ability to bind latex particles to the cell surface. This study demonstrates the presence of phagocytic leukemic B lymphocytes in addition to hairy cells, and should strengthen the evidence that hairy cells are lymphocytes in the pathway of B-cell differentiation. (21 refs)

79-1042 Multiple Heavy Chain Isotypes on the Surface of the Cells of Hairy Cell Leukemia. (Eng)

Burns, G. F. (Dept. Haematological Medicine, Univ. Clinical Sch., Hills Rd., Cambridge CB2 2QL, England); Cawley, J. C.; Worman, C. P.; Karpas, A.; Barker, C. R.; Goldstone, A. H.; Hayhoe, F. G. *Blood* 52(6): 1132-1147; 1978.

The mononuclear cells of 15 patients with hairy-cell leukemia were studied for expression of surface membrane immunoglobulin (SIg). SIg of restricted light chain type (10 K:5 λ) was found in all cases. As for heavy chain isotype expression, in seven cases the cells expressed only IgG (6 κ , 1 λ : Type I); seven cases showed three or four isotypes that always included both M and D (3 κ , 4 λ : Type II), and one case showed the combination of M and D alone (κ : Type III). Although wide variations were observed in the percentage of SIg expression and in the relative proportions of the different heavy chain isotypes (Type II) for a single patient at different times, the cells maintained the same isotypes, and the major heavy chain type was consistently expressed on approx the same percentage of cells as bore the exclusive light chain type. SIgD was reexpressed slowly after stripping. The demonstration of cytoplasmic IgG, the presence of IgG in the supernatant of cultured cells, and the observed increase in SIgG rosette formation with time in culture suggested that at least some hairy cells secrete IgG. The presence of multiple heavy chain isotypes on hairy cells seems to place them late in B cell ontogeny. (59 refs)

79-1043 Terminal Deoxynucleotidyl Transferase (TdT), Cytochemistry, and Membrane Receptors in Adult Acute Leukemia. (Eng) Gordon, D. S. (Immunology Div., Bureau Labs., Center Disease Control, 1600 Clifton Road, N. E., Atlanta, GA, 30333); Hutton, J. J.; Smalley, R. V.; Meyer, L. M.; Vogler, W. R. *Blood* 52(6): 1079-1088; 1978.

Terminal deoxynucleotidyl transferase (TDT) activity, immunologic membrane markers, and cytochemical reactivity

were examined in blasts from 80 adults with acute leukemia. TDT was uniformly elevated in all 8 patients with null-cell and T-cell lymphoblastic leukemia, in both patients with null-cell lymphoma, and in 3/27 patients with acute myeloblastic leukemia. TDT activities were low in 24/27 patients with acute myelomonocytic, acute monocytic, and lymphoma leukemia of B- or T-cell type. Blasts from 17 patients did not show distinctive patterns of cytochemical staining; these patients were classified as having acute undifferentiated leukemia. For nine of these patients there was disagreement within a panel of four hematologists as to whether the leukemia should be classified morphologically as lymphoid or nonlymphoid. Especially in such cases, the use of cytochemical techniques, immunologic membrane markers, and TDT determinations offer objective methods for diagnosis of acute leukemia and are likely to be of clinical relevance. (27 refs)

79-1044 Angioimmunoblastic Lymphadenopathy: Evolution to a Burkitt-Like Lymphoma (Meeting Abstract). (Eng) Mazur, E. M. (Dept. Medicine, Yale Univ. Sch. Medicine, New Haven, CT); Lovett, D. H.; Enriquez, R. E.; Papac, R. J. *Clin Res* 26(4): 619A; 1978. (no refs)

79-1045 Physical Association of Histocompatibility Antigens and Tumor-associated Antigens on the Surface of Murine Lymphoma Cells. (Eng) Callahan, G. N. (Dept. Molecular Immunology, Scripps Clinic and Res. Foundation, 10666 N. Torrey Pines Road, La Jolla, CA, 92037); Allison, J. P.; Pellegrino, M. A.; Reisfeld, R. A. *J Immunol* 122(1): 70-74; 1979.

Serologic and immunochemical techniques were used to characterize plasma membrane antigens of the murine estrogen-induced lymphoma 6C3HED. Syngeneic C3H/HeJ anti-6C3HED antisera were prepared and were shown by cytotoxicity, absorption, and immunoprecipitation tests to be specifically reactive with the lymphoma cells. These sera, therefore, appeared to detect a tumor-associated antigen (TAA) of the 6C3HED lymphoma. Alloantisera to H-2.23 antigens were unreactive with intact lymphoma cells by cytotoxicity and absorption assays. However, H-2.23 antigens were detectable in tumor cell lysates by inhibition of cytotoxicity and immunoprecipitation. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) of immunoprecipitates of radiolabeled tumor cell extracts obtained with anti-6C3HED and anti-H-2.23 antisera gave patterns that were essentially identical and had peaks corresponding to proteins with mol wts of 70,000, 45,000, and 12,000. Antigens reactive with both antisera were found to be present on the cell surface. An immunoadsorbent of insolubilized anti-6C3HED removed H-2.23 antigens detectable in lymphoma extracts but had no effect on H-2.23 antigens in normal splenocyte extracts. These data indicate that H-2.23 and TAA are physically associated on 6C3HED cells. This association might be important in the development of

host immunity or in the breakdown of some of the normal cell-cell interactions and control processes that accompany tumorigenesis. (21 refs)

- 79-1046 Hodgkin's Disease. T-Cell Defect in Patients in Complete Remission.** (Fre) Lang, J. M. (Clinique des Maladies du Sang, Centre Hospitalo-Universitaire de Strasbourg, 1, place de l'Hopital, 67005 Strasbourg Cedex, France); Bigel, P.; Oberling, F.; Mayer, S. *Sem Hop Paris* 54(37-40): 1155-1158; 1978.

The T-lymphocyte level was studied in 11 patients (6 men, 5 women) with Hodgkin's disease in complete remission 6-72 mo after the end of 0.5-3 yr of maintenance therapy. Seven patients were initially in Stages III and IV. The peripheral blood lymphocyte count was $< 1,200/\text{mm}^3$ in 5/11 patients. The absolute numbers of erythrocyte (E)-rosette-forming T-lymphocytes were reduced in 8 patients ($248-595/\text{mm}^3$), and the active E-rosette count was reduced in 3/7 patients tested (19%-26%, vs a normal value of 37%). The EAC (erythrocyte antibody complement) rosette count was slightly increased in two patients only (37%, vs a normal value of 24%). In vitro stimulation with a suboptimal dose of phytohemagglutinin was studied in 9 patients and in 19 healthy controls. A statistically significant deficiency of lymphocyte transformation was found that may be due to a membrane change rather than to a true decrease in this reaction. (20 refs)

- 79-1047 Autoimmune Hemolytic Manifestations Associated with Hodgkin's Disease.** (Ita) Boccardi, V. (Istituto di Patologia Medica I, Universita, Rome, Italy); Girelli, G.; Anselmo, A. P.; Mandelli, F. *Recent Prog Med (Roma)* 64(4): 446-454; 1978.

The association of autoimmune hemolytic anemia (AHA) with Hodgkin's disease (HD) was studied in 100 patients with HD. AHA was found in seven cases (4 men and 3 women). Twenty-seven patients were kept under observation because of anemia: AHA was diagnosed in 4 of them. The other 73 patients were subjected to systematic screening for signs of autoimmunization regardless of anemia; AHA was found in 3 of them. Six of the seven patients presented with anemia 2-7 yr after the onset of HD, the seventh patient developed HD 3 yr after the onset of chronic idiopathic anemia. AHA preceding HD can be explained by the immune surveillance theory, according to which the defect responsible for the insurgescence of the neoplasia resides in the inability to terminate the lymphoproliferative process induced by an antigenic stimulation. There is as yet no satisfactory theory to explain AHA associated with HD given the diversity of chronology between the two conditions. (56 refs)

- 79-1048 Hematologic Changes During Spleen Colony Development in Nonirradiated Mice.** (Eng) Tamai, M. (Inst. Cancer Res., Medical Sch., Osaka Univ., Nakanoshima 4-chome, Kita-ku, Osaka 530, Japan); Kitamura, Y. *Blood* 52(6): 1148-1155; 1978.

The mechanism of spleen colony formation in nonirradiated mice was investigated in a time-course study. When the spleen cells of C57BL mice immunized against CBA-T6T6 mice were injected into nonirradiated BT6F₁ (C57BL x CBA-T6T6) hybrid mice, the number of hematopoietic stem cells [colony forming unit-stem cells (CFU-S) of C57BL mouse origin that settled in the spleen of the BT6F₁ mice continued to decrease in the first 9 days and then started to increase, with a doubling time of about 36 hr. Colonies were detected on the surface of the spleen 16-22 days after the cell injection. The slower appearance of spleen colonies in nonirradiated mice (compared with 6-10 days in the irradiated animals) appears to be due to the delayed start of differentiation and to the prolonged doubling time of CFU-S in nonirradiated mice. It is suggested that CFU-S are stimulated into proliferation to repair the decrease of CFU-S caused by immune reactions between host and donor cells, that donor CFU-S replace host CFU-S during the first 9 days after injection of parental spleen cells, and that subsequently, the donor CFU-S can initiate growth like CFU-S injected into lethally irradiated mice. (17 refs)

- 79-1049 Serological Identification of Neoantigens on Mouse Fibroblasts Which Have Undergone "Spontaneous" Malignant Alteration In Vitro.** (Eng) Wil-lumsen, B. M. (Fibiger-Lab., Ndr. Frihavns-gade 70, DK. 2100 Copenhagen 0, Denmark); Ulrich, K.; Kieler, J. *Int J Cancer* 23(2): 209-216; 1979.

Two malignant cell lines result from the spontaneous transformation of ST/a mouse lung fibroblasts in vitro. ST-L1 cells produce tumors only in newborn or immunodepressed syngeneic (SG) mice and ST-L22 cells produce tumors in SG hosts irrespective of age and immunocompetence. Both lines produce nontransforming C-type virus. Neoantigens expressed on ST-L1 cells were analyzed by characterizing the reactivities present in SG anti-ST-L1 antiserum (obtained by hyperimmunizing ST/a mice with an sc injection of ST-L1 cells). Sera from mice that rejected ST-L1 showed reactivity toward the structural murine leukemia virus proteins gp70 and p15(E). Radioimmunoassay showed that ST-L1 and ST-L22 contained the same amount of p30 determinants, but that the latter contained a threefold lower concentration of gp70 determinants. Upon gel electrophoresis, there was a qualitative difference in the mobility of the glycoproteins found in virus particles from both lines. These quantitative and qualitative differences in gp70 expression may account for the different immunogenicity of the cell lines in SG hosts, in which only ST-L1 cells give rise to antibodies toward gp70. However, the complete absorption of anti-ST-L1 reactivity

by large amounts of ST-L22 shows that all antigenic determinants in ST-L1 are present in ST-L22. Either the presentation of the antigens is changed markedly in ST-L1 cells, leading to a disproportionately increased immunogenicity of gp70, or the rate at which gp70 is shed from the cell surface may be higher on ST-L1 cells than on ST-L22 cells. No virus-induced nonviral antigens or serologically detectable, cellularly determined neoantigens were expressed on ST-L1 cells. ST-L1 cells evoke a humoral and a rejection response when injected into SG-mice. It is not known whether identical antigens trigger these responses. (32 refs.)

- 79-1050 Morphology of Lymphoreticular Tissues in Mice with Reticulosarcoma.** (Eng) Pavelic, Z. P. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., Buffalo, NY, 14263); Boranic, M.; Pavelic, K. *Exp Pathol (Jena)* 15(5): 288-295; 1978.

Transplantation of a syngeneic reticulosarcoma with weak transplantation antigenicity into C57BL mice produced a vigorous histological response in regional lymph nodes and a slight response in nonregional lymph nodes and spleen. Mesenteric lymph nodes and the thymus did not respond. Morphological and gravimetric changes indicated that both regional and nonregional lymph nodes and the spleen take part in the host immune response. (14 refs)

- 79-1051 Evidence for the Expression of Human Tumor-specific Antigens Associated with β_2 -Microglobulin in Human Cancer and in Some Colon Adenomas and Benign Breast Lesions.** (Eng) Thomson, D. M. (Montreal General Hosp. Res. Inst., 1650 Cedar Ave., Montreal, Quebec, Canada H3G 1A4); Tataryn, D. N.; O'Connor, R.; Rauch, J.; Friedlander, P.; Gold, P.; Shuster, J. *Cancer Res* 39(2, part 1): 609-611; 1979.

The blocking tube leukocyte adherence inhibition (LAI) assay was used to monitor the purification of human tumor-specific antigens (TSA's) from colon and breast neoplasms and malignant melanoma. An attempt was made to determine if some benign breast tumors and adenomatous polyps express the same organ type-specific neoantigens as do cancers derived from the same organ. The tumor antigens were specific for the organ from which the cancer arose and the histopathology of the cells of origin. Immunochemical studies revealed that TSA's could be water-solubilized from cancer cell membranes by limited papain digestion; on Sephadex G-150 chromatography, most of the TSA eluted in the mol wt range 70,000-150,000. Affinity chromatography with anti-human β_2 -microglobulin (β_2m) antiserum indicated that the TSA's contain a β_2m subunit. The specificity of binding of the TSA to the anti- β_2m immunoadsorbent affinity column and the immunologically specific abrogation of LAI activity were shown. Some patients with either adenomatous

polyps or benign breast disease showed LAI activity to phosphate-buffered saline extracts of colon and breast cancer, respectively, but did not react to extracts of normal colon mucosa or breast tissue. Moreover, the LAI-reactive WBC were blocked by the papain-soluble TSA's from colon and breast cancer, respectively, purified by anti- β_2m chromatography. These studies suggest that some "benign" lesions express TSA's before the appearance of morphological evidence of cancer. They also indicate that the putative TSA's of cancers of different organs are similar in subunit structure, size, and genetic linkage and have some unexplained relationship to organ definition. - 79-1052 Suppression of Malignancy in Mouse-Man Hybrid Cells.** (Eng) Louis, C. J. (Dept. Pathology, Univ. Melbourne, Austin Hosp., Heidelberg, Victoria, Australia); Rose, G. B. *Pathology* 10(4): 343-350; 1978.

Somatic cell hybrids were prepared by fusing malignant mouse melanoma cells (PG19) with diploid human lymphocytes and fibroblasts in the presence of inactivated Sendai virus. Clones of hybrid cells differed with respect to their number of chromosomes; in particular, human chromosomes (HuC) were preferentially lost and mouse chromosomes retained. Hybrid clones containing a range of HuC were selected and assayed for tumorigenicity in female nude mice, and the presence or absence of specific HuC was correlated with malignancy. PG19 cells (1×10^5 sc) produced progressive tumors in 5/5 nude mice. Normal human lymphocytes and normal human fibroblasts (both 1×10^6 sc) failed to produce tumors. No hybrids from PG x fibroblast crosses (1×10^6 cells sc) induced tumors in nude mice over a 4-mo period. Only PG19 x lymphocyte hybrids, which contained six or less HuC, produced tumors, the tumor yield being inversely related to the number of HuC present. However, the overall tumorigenicity was considerably reduced from that of the parent melanoma cell line. Chromosome analyses, using the parentine fluorescence banding technique, failed to localize the suppressive effect to a specific chromosome. (18 refs)

- 79-1053 Human Peripheral Null Lymphocytes: Ultrastructural Aspects of the "K" Cell Effect Against a Melanoma Target Cell.** (Eng) Cesarini, J. P. (Laboratoire de Recherche sur les Tumeurs de la Peau Humaine, Fondation A. de Rothschild, 29 rue Manin, 75019 Paris, France); Roubin, R.; Kalden, J. R.; Peter, H. H. *Biomedicine* 28(4): 219-225; 1978.

The Fc-receptor-bearing killer (K) cells in a human null cell lymphocyte fraction, which exhibited cytotoxic activity against antibody-sensitized human melanoma target cells, was characterized ultrastructurally. The homogeneous population of mononuclear cells found in close contact with the target cells was 8-10 μ m in diameter, with an irregular nu-

cleus, discrete rough endoplasmic reticulum, isolated ribosomes, a large cytoplasm, and a ruffling membrane in close contact with the tumor cell. (30 refs)

- 79-1054 Association of Melanoma Tumor Antigen Activity with β_2 -Microglobulin.** (Eng) Malley, A. (Dept. Immune Diseases, Oregon Regional Primate Res. Center, Beaverton, OR, 97005); Burger, D. R.; Vandembark, A. A.; Frikke, M.; Finke, P.; Begley, D.; Acott, K.; Black, J.; Vetto, R. M. *Cancer Res* 39(2, part 2): 619-623; 1979.

The relationship between β_2 -microglobulin (β_2m) and melanoma tumor antigen (MTA) present in KCl extracts of freshly excised tumor tissue was evaluated. Most MTA activity present in the melanoma extracts bound to a Sepharose-anti- β_2m adsorbent. This association was not due to the presence of histocompatibility locus antigens (HLA) in the extract. Removal of HLA antigens from the KCl extracts by KBr flotation did not reduce the MTA activity of the extracts, and the MTA activity still appeared to be associated with β_2m . The complete blocking of MTA activity by pre-treating the anti- β_2m adsorbent with β_2m and the lack of detectable MTA binding to a Sepharose anti-normal human serum adsorbent demonstrated the specificity of the binding of MTA to the anti- β_2m adsorbent. The data suggest that β_2m provides the means for MTA and other proteins to become associated with lymphocyte cell surfaces. (16 refs)

- 79-1055 Malignant Angioendothelioma--Effect of Immunotherapy with *Corynebacterium parvum*.** (Eng) Tan, S. G. (Dept. Dermatology, General Infirmary Leeds, Leeds, England); Cotterill, J. A.; Roberts, M. M.; Cunliffe, W. J. *Acta Derm Venereol (Stockh)* 58(6): 551-553; 1978.

A 76-yr-old man with malignant angioendothelioma of the scalp was given adjunct *Corynebacterium parvum* intralesional immunotherapy. Although the patient died before the effect of the *C. parvum* could be assessed adequately, compared with uninjected tumor sites, sections of the injected sites showed a much greater degree of necrosis with an associated neutrophil polymorph infiltrate, but no lymphocytic reaction. - 79-1056 Enhancement of Resistance to Murine Osteogenic Sarcoma In Vivo by an Extract of *Brucella abortus* (Bru-Pel): Association with Activation of Reticuloendothelial System Macrophages.** (Eng) Glasgow, L. A. (Dept. Pediatrics, Univ. Utah Coll. Medicine, Salt Lake City, UT, 84132); Crane, J. L.; Schleupner, C. J.; Kern, E. R.; Youngner, J. S.; Feingold, D. S. *Infect Immun* 23(1): 19-26; 1979.

The capacity of an aqueous-ether-extracted residue of *Brucella abortus* (Bru-Pel) to enhance host resistance to the development of a transplantable osteogenic sarcoma (OGS) was investigated along with its antitumor and antiviral activity. C57Bl/6J mice were inoculated with Bru-Pel (1,000 μ g ip) either 14 days before, immediately preceding (day 0), or 3 or 7 days after ip inoculation with 10^5 OGS cells. After 2 mo of observation, the mortality of tumor-inoculated mice was significantly reduced when Bru-Pel was given on day -14, 0, or +3, but not on day +7. *Corynebacterium parvum* (1,400 μ g ip) was also effective when given on day -14 or 0, but two interferon inducers failed to give any protection against tumor development. Peritoneal macrophages harvested from mice that had received Bru-Pel were cytotoxic for OGS cells in vitro, limited the replication of vaccinia virus in cell cultures, and demonstrated enhanced emissivity of chemiluminescence during phagocytosis of zymosan particles of *Candida albicans*. Bru-Pel-activated macrophages were also cytotoxic for syngeneic mouse embryo fibroblasts; the reason for this effect is not known. Bru-Pel-treated mice had a markedly enhanced resistance to mortality from *Listeria monocytogenes*. These observations support the hypothesis that Bru-Pel shares a number of characteristics with recognized immunomodulating agents and that one mechanism by which it modulates host resistance is activation of macrophages of the reticuloendothelial system. (32 refs)

- 79-1057 Suppressive Versus Augmenting Effect of the Same Pretreatment Regimen in Two Murine Tumor Systems with Distinct Effector Mechanisms.** (Eng) Fufiwaru, H. (Inst. Cancer Res., Osaka Univ. Medical Sch., Fukushima 1-1-50, Fukushima-ku, Osaka 533, Japan); Hamaoka, T.; Kitagawa, M. *Gann* 69(6): 793-803; 1978.

The effect of presensitization with x-irradiated tumor cells on the development of the host's immune resistance against the tumor-associated transplantation antigens was investigated using the X5563 plasmacytoma and MM102 mammary tumor systems (both of C3H/He origin) in C3H/He mice. The acquisition of T-cell-mediated immune resistance against the X5563 plasmacytoma was suppressed in syngeneic mice pre-treated with x-irradiated X5563 cells. The development of an immune cell population was inhibited by serum factors but not by suppressor cells. When the serum factor mediating this tumor-specific suppression was fractionated on a Sephadex G-200 column, the suppressive activity was found in the albumin-corresponding fraction and was free of IgG and IgM. In the MM102 mammary tumor system, in which immune resistance is mediated solely by tumor-specific antibody, pre-treatment with x-irradiated MM102 cells eventually augmented the induction of anti-tumor immunity without any enhancement of tumor growth. The results indicate that tumor antigens given by the same presensitization regimen have different effects on the distinct effector mechanisms of two different tumor systems of the same syngeneic mice. (29 refs)

79-1058 Granuloerythropoietic Colonies in Human Bone Marrow, Peripheral Blood, and Cord Blood.

(Eng) Fauser, A. A. (Ontario Cancer Inst., 500 Sherbourne St., Toronto, Ontario M4X 1K9, Canada); Messner, H. A. *Blood* 52(6): 1243-1248; 1978.

Conditions supporting the growth of granuloerythropoietic colonies [colony-forming unit (CFU)-G/E] in specimens of human bone marrow, peripheral blood, and cord blood are reported. Colony growth is promoted by media conditioned by WBC in the presence of phytohemagglutinin and by the addition of erythropoietin to the cultures on days 4 or 5. Sedimentation velocity profiles suggest that the colonies originate from single cells (CFU-G/E) rather than from doublets or clumps. This hypothesis is supported by cocultivation of male and female specimens. Cells in the granuloerythrocytic colonies that developed in these mixing experiments were either uniformly female by Y-chromatin analysis or they contained Y-chromatin bodies in both the granulocytic and erythroid cells. (14 refs)

79-1059 A Nude Mouse with Enlarged Thymic Rudiment. (Eng) Imamura, N. (Dept. Pathology,

Res. Inst. Nuclear Medicine and Biology, Hiroshima Univ., Kasumi 1-2-3, Hiroshima 734, Japan); Yokoro, K. *Gann* 69(6): 859-860; 1978.

The immunohistology of an enlarged thymic rudiment in a nude mouse was studied. The animal was killed 3 mo after sc inoculation with chemically-induced rat leukemic cells. No take of the leukemic transplant was evident at autopsy, and there was no ectopic thymus around the neck of the mouse. Twenty-five percent of the animal's spleen cells expressed Thy-1.2 antigen, compared with <7% of most nude mice. The thymus-like tissue showed no lymphocyte proliferation, and it was histologically embryonal. The thymus-dependent lymphoid tissue showed an increased small lymphocyte population relative to other nude mice. The data suggest that the embryonal thymus possesses the ability to induce T-cell differentiation. (5 refs)

79-1060 Thymic Deficiency in Down's Syndrome. (Eng)

Levin, S. (John Askin Labs., Pediatric Res. Dept., Kaplan Hosp., Rehovot, Israel); Schlesinger, M.; Handzel, Z.; Hahn, T.; Altman, Y.; Czernobilsky, B.; Boss, J. *Pediatrics* 63(1): 80-87; 1979.

Histologic studies were made of the thymuses of 12 infants with Down's syndrome (DS) and 12 infants without DS who were matched for age and, as closely as possible, for cause of death and length and nature of terminal illness. Immunologic studies were made of the blood of 20 infants and children with DS (age range 1 day to 10 yr) and of the cord blood of 8 newborns with DS. Results of some immunologic studies of 12 adult patients with DS are also included. The

mean wt of the DS thymuses was 3.3 g vs 5.6 g for control thymuses. Almost every DS thymus was histologically abnormal, demonstrating lymphocyte depletion, diminution of the cortex, and loss of corticomedullary demarcation, changes resembling thymic involution. In addition, Hassall's corpuscles were markedly enlarged, and some were surrounded by a sheath of lymphocytes. Immunologically, there was a significantly lower percentage of T cells in the peripheral blood of DS patients than in the blood of normal controls. The mean lymphocyte count of these patients was also lower than control values, but the differences were not statistically significant. Children and newborns with DS exhibited a markedly diminished response to phytohemagglutinin (PHA), but adults with DS did not show this decrease. PHA-stimulated immune interferon production and polyinosinic-polycytidylic acid-stimulated classic viral interferon production were also significantly diminished in patients with DS. The deficient cell-mediated immune system could explain some of the abnormal clinical findings in DS patients, such as increased respiratory infections and lymphatic leukemia. (42 refs)

79-1061 Influence of Inoculation Site on Development of the Lewis Lung Carcinoma and Suppressor Cell Activity in Syngeneic Mice. (Eng) Malave, I. (Dept. Experimental Medicine, Instituto Venezolano de Investigaciones Cientificas, Apartado 1827, Caracas 101, Venezuela); Blanca,

I.; Fuji, H. *J Natl Cancer Inst* 62(1): 83-88; 1979.

The growth of the Lewis lung carcinoma (3LL) was studied in syngeneic C57BL/6 mice inoculated sc with similar numbers of tumor cells in either the flank or the hind footpad (fp). After injection of small numbers of 3LL cells (10^3 or 10^4), the incidence of tumors was lower in the flank than in the fp. However, after a successful 3LL transplant, tumors in the flank progressed faster than those in the fp, as evidenced by the early metastatic dissemination to the lungs and the shorter survival of the hosts. Local adoptive transfer tests demonstrated the early appearance of suppressor cell activity in spleens from mice bearing tumors in the flank. Adult thymectomy as well as treatment with antithymocyte serum after the tumor transplant inhibited the growth of a flank tumor but did not modify significantly that of an fp tumor. Thus, variations in the site of an sc tumor implant resulted in differences in tumor development that appeared to depend on the characteristics of the immune response elicited by the inoculum. (34 refs)

79-1062 The Assessment of Antichymotrypsin in Cancer Monitoring. (Eng) Kelly, U. L. (Dept. Cancer Res., Univ. Leeds, Leeds LS2 9NL, England); Cooper, E. H.; Alexander, C.; Stone, J. *Biomedicine* 28(4): 209-215; 1978.

Serum levels of antichymotrypsin (ACT), antitrypsin (AT), and α_1 -acid glycoprotein (AGP) were compared in 680 samples taken from normal donors, cancer patients at various

stages of disease, and cancer patients apparently cured after tumor excision. In all invasive cancers, the median levels of these three acute-phase reactant proteins were increased over control values. According to preliminary data, the relative frequency distribution of ACT in early and advanced metastatic colorectal cancer and invasive bladder cancer was bimodal. The bladder cancer data suggested that the ACT level rises with an increasing tumor load. Longitudinal studies of patients who had undergone tumor excision revealed that after recovery from the surgery, ACT, in common with the other two proteins, was very stable until the development of a recurrence or metastases. Prostate and breast cancer patients placed on estrogen therapy showed a decrease in ACT after therapy initiation, partly due to tumor remission and partly due to a direct estrogen effect. The normal donors, unlike the cancer patients, had a normal distribution of ACT. This, plus the fact that the protein shows no phenotypic variation, indicates that ACT is a good candidate for inclusion in a multivariate system for tumor monitoring. (12 refs)

79-1063 Characterization of Murine Tumor-associated Antigens by the Micro-leukocyte Adherence Inhibition Assay. (Eng) Howell, J. H. (Dept. Surgical Oncology, Roswell Park Memorial Inst., Buffalo, NY, 14263); Russo, A. J.; Goldrosen, M. H. *Cancer Res* 39(2, part 1): 612-618; 1979.

The micro-leukocyte adherence inhibition (LAI) assay was used to monitor the solubilization and purification of tumor-specific antigens from a murine colonic adenocarcinoma (MCA-38) and from a spontaneous murine melanoma (B16), both syngeneic to C57BL/6J mice. Three extraction procedures were performed on the membrane preparations of the tumors: 1 M perchloric acid (PCA), 3 M KCl, and deoxycholate solubilization followed by brief papain treatment. The deoxycholate/papain extract was without activity in the LAI assay; however, significant recognition of the former two extracts was observed with peritoneal cells from tumor-bearing mice. The lack of appreciable activity in the detergent- and papain-solubilized material suggests that the antigen detected in the LAI assay is not similar to murine histocompatibility (H-2) antigens, since this solubilization procedure has previously provided excellent yields of H-2 antigens. Plasma membrane vesicles prepared from cultured tumor cells also

demonstrated specific antigenic activity. The PCA extract of MCA-38 tumor was fractionated on Bio-gel P-200 and on Sephacryl S-200, and the LAI reactivity was found in a fraction with a mol wt > 160,000. A rabbit antiserum to the 1 M PCA extract of MCA-38 tumor was prepared, and after solid state absorption with 1 M PCA extracts of C57BL/6J murine colon, liver, and kidney, no Ouchterlony immunoprecipitation activity was observed against the P-200 fraction containing the LAI reactivity. Immunoprecipitation was obtained with the PCA fraction with a mol wt of 45,000-158,000. This material is heat-stable, and it migrated as a β -protein in immunoelectrophoresis. These results suggest that the MCA-38 colon carcinoma contains a glycoprotein with some carcinoembryonic antigen-like properties, as well as a distinct specific tumor-associated antigen recognized in the LAI assay. PATHOGENESIS

- 79-1064 Genetic Material and Cancer: Genetics of Cancer.** (Fre) Jami, J. (No affiliation given). *Lyon Med* 240(16): 280-282; 1978.

A brief description is given of hybridization studies in which normal and malignant (fibrosarcoma) mouse cells were crossed. The hybrid cell, which was malignant (produced tumors in mice), contained genetic information that was not present in the normal cell. Further studies using human cells are proposed. (no refs)

- 79-1065 Erythropoietin (Ep) Dose-Response Curves for Three Classes of Erythroid Progenitors in Normal Human Marrow and in Patients with Polycythemia Vera.** (Eng) Eaves, C. J. (Medical Biophysics Unit, British Columbia Cancer Res. Centre, 601 W. 10th Avenue, Vancouver B.C., Canada V5Z 1L3); Eaves, A. C. *Blood* 52(6): 1196-1210; 1978.

Three classes of normal human erythropoietic progenitor cells were studied with respect to their erythropoietin (Ep) sensitivity under various culture conditions. Dose-response curves extending from 0.001 to 10 units Ep/ml indicated that, under optimal conditions, the formation of very large erythroid colonies (or "bursts") [from primitive burst-forming units-erythroid (BFU-E)] required about 3-fold more Ep than that needed for small bursts from mature BFU-E and about 5-fold more Ep than that needed for the production of small erythroid clusters [from colony-forming units-erythroid (CFU-E)]. Removal of the adherent marrow cell fraction and/or omission of leukocyte-conditioned medium from the cultures resulted in failure to achieve maximum burst formation by primitive BFU-E. The effect was not as great on mature BFU-E and was minimal on CFU-E. Ep dose-response curves indicated two coexisting populations in polycythemia vera (PV): one with hyper-Ep-responsive cells and one with normal in vitro Ep sensitivity. There was a progressive increase in favor of the abnormal cells in the later, mature BFU-E and CFU-E compartments. The data suggest that RBC precursors show progressive changes in their response to Ep and other factors that affect burst formation in vitro. With regard to PV, there may be a growth advantage of the abnormally Ep-sensitive line proliferating in a low Ep environment. (23 refs)

- 79-1066 Relationship Between Serum Iron, Plasma Iron Disappearance Rate, and Plasma Iron Turnover in Various Hematologic Diseases.** (Jpn) Saito, H. (Radiology

Dept., Nagoya Univ. Hospital, 65 Tsurumai-cho, Showa-ku, Nagoya 466, Japan). *Radioisotopes* 27(11): 656-658; 1978.

The relationship between serum iron, plasma iron disappearance rate (PIDR), and plasma iron turnover was determined for 26 patients with hematologic diseases, including aplastic anemia, hypoplastic anemia, hemolytic anemia, paroxysmal nocturnal hemoglobinuria, hereditary spherocytosis, and polycythemia vera. In general, when serum iron was increased, the PIDR was elevated, and when serum iron was decreased, the PIDR was low. In both situations, the plasma iron turnover was not affected. However, these situations did not hold for all the hematologic diseases, and exceptions are described. (6 refs)

- 79-1067 Feline Preleukemia: An Animal Model of Human Disease.** (Eng) Maggio, L. (Dept. Medicine, Sch. Veterinary Medicine, Univ. Pennsylvania, Philadelphia, PA); Hoffman, R.; Cotter, S. M.; Dainiak, N.; Mooney, S.; Maffei, L. A. *Yale J Biol Med* 51(4): 469-476; 1978.

A naturally occurring syndrome in domestic cats that resembles human preleukemia is described. Twelve cats (9 males, 3 females) were evaluated for lethargy, anorexia, and wt loss. Mucous membrane pallor was present in eight, fever in eight, and hepatosplenomegaly in six. All animals were anemic (mean hematocrit: 14.5%), and anemia was severe in four animals. Although macrocytosis without polychromasia was occasionally evident in the peripheral blood smear, normochromic, normocytic RBC morphology was the rule. Nucleated RBC precursors were observed in 10 animals. WBC abnormalities at presentation were confined to leukopenia with granulocytopenia. Only two cats were feline leukemia virus (FeLV)-negative at presentation. These two became viremic when they developed overt leukemia. Four of eight bone marrow aspirates showed mild to moderate lymphocytosis. The time interval from the development of anemia to the diagnosis of overt leukemia varied from 1 wk to 33 mo. The natural occurrence of this syndrome in this domestic animal population makes it a potential model of human preleukemia. (46 refs)

- 79-1068 Preleukemic Syndrome. Hematopoietic Dysplasia.** (Ita) Majolino, I. (Universita degli Studi, Pavia, Italy); Panizza, P.; Nalli, G.; Trpin, L.; Barosi, G.; Ascari, E. *Recent Prog Med (Roma)* 64(4): 404-445; 1978.

Studies and observations on hematopoietic dysplasia as

preleukemic syndromes are reviewed, and new cases are presented. Sideroblastic anemia was diagnosed in three men aged 64, 54 and 64 yr a few months before they developed leukemia. Paroxysmal nocturnal hemoglobinuria was diagnosed in a 34-yr-old man nearly 2 yr before he developed leukemia. Aplastic anemia preceded leukemia in a 16-yr-old man and a 67-yr-old woman. Refractory anemia was diagnosed in two women aged 23 and 72 yr and two men aged 55 and 65 yr before they developed leukemia. One of the two men was a radiologist. (180 refs)

- 79-1069 Childhood Leukemia Presenting as a Diaphyseal Radiolucency.** (Eng) Bos, G. D. (Section Orthopedic Surgery, Pritzker Sch. Medicine, Univ. Chicago, Box 421, 950 E. 59th St., Chicago, IL, 60637); Simon, M. A.; Spiegel, P. G.; Moohr, J. W. *Clin Orthop* (135): 66-68; 1978.

The case of a 41-mo-old boy with leukemia who presented with a symptomatic diaphyseal destructive lesion of the femur is reported. At presentation, pain in both thighs and pyrexia were the only symptoms. A bone scan showed increased uptake in one femur. Biopsy demonstrated numerous blast cells compatible with acute lymphocytic leukemia. (10 refs)

- 79-1070 Sister Chromatid Exchanges and Chromosomes in Chronic Myelogenous Leukemia and Cancer Families.** (Eng) Cheng, W. S. (Medicine Branch, NCI, Bethesda, MD, 20014); Mulvihill, J. J.; Greene, M. H.; Pickle, L. W.; Tsai, S.; Whang-Peng, J. *Int J Cancer* 23(1): 8-13; 1979.

Banded karyotypes and baseline frequencies of sister chromatid exchanges (SCE) were studied in blood lymphocytes from 96 individuals: 7 patients with chronic myelogenous leukemia (CML), 15 normal controls, and 5 "cancer families" comprising 12 cancer patients, 40 tumor-free blood relatives, and 22 spouses. The diseases in each family consisted of malignant melanoma, Epstein-Barr virus-associated malignancies and a birth defect syndrome, non-Hodgkin lymphoma and diverse carcinoma, Hodgkin's lymphoma and adenocarcinomas, and acute myelogenous leukemia. In addition to the presence of the Philadelphia chromosome in the patients with CML, karyotypic abnormalities, especially breaks and fragments, occurred in 29% of the cancer family members, but they were inconsistent and usually attributable to radiotherapy. Mean SCE values were normal in CML, but were low (by t-test) in the cancer family tumor patients combined ($p = 0.026$) and in their blood relatives. In the tumor patients, mean levels of SCE declined with increasing age ($p = 0.03$). After adjusting for this age effect, no significant differences remained among groups. In patients at high risk of cancer (ie, because they had CML or a strong family history of cancer), spontaneous SCE rates were not a marker of cancer risk. (27 refs)

- 79-1071 Bullous Pyoderma Gangrenosum and Acute Leukemia.** (Eng) Sheps, M. (Nurses' Residence, No. 202, 399 Bathurst St., Toronto, Ontario, Canada M5T 2S8); Shapero, H.; Ramsay, C. *Arch Dermatol* 114(12): 1842-1843; 1978.

Two episodes of bullous pyoderma gangrenosum (BPG) occurred in a 33-yr-old woman, one several months before evidence of leukemia appeared and one concurrently with acute myelogenous leukemia. A skin biopsy early in the second episode showed a panniculitis, with a predominance of polymorphonuclear WBC invading the fat septa. It is suspected that the first illness was acute leukemia and that the systemic steroids used to control the BPG also induced remission of the leukemia. (7 refs)

- 79-1072 Absence of Late-replicating X-Chromosome in a Female Patient with Acute Myeloid Leukemia and the 8;21 Translocation.** (Eng) Levan, G. (Dept. Genetics, Univ. Gothenburg, S-414 63 Gothenburg, Sweden); Mitelman, F. *J Natl Cancer Inst* 62(2): 273-275; 1979.

An attempt was made to determine the status of activity of the remaining X chromosome in women with acute myeloid leukemia (AML) characterized by the 8;21 translocation and the loss of one X chromosome. To study late DNA replication, a complete karyotype analysis plus continuous labeling autoradiography were performed on 19 cells of a 41-yr-old female AML patient. This was done during partial remission, when the bone marrow contained cells with both 45 and 46 chromosomes. In all XO cells analyzed, the single X was always early-replicating; ie, it was the active X chromosome. It is suggested that in patients housing AML with the 8;21 translocation, loss of the inactive X chromosome in women and the Y in men (which occurs in approx 50% of patients) entails selective advantage to the stemline. The most likely explanation for the absence of the late-replicating X chromosome in this study is that this chromosome was lost from a single cell and that the stemline population developed from this cell. - 79-1073 Systemic Lupus Erythematosus and Malignant Histiocytosis (Letter to Editor).** (Eng) Fournie, G. J. (Laboratoire d'Immunopathologie Renale, Service de Nephrologie et d'Hemodialyse, C.H.U. Toulouse-Purpan, 31052 Toulouse, France); Conte, J. J.; Delsol, G.; Fabre, J.; Miguieres, J.; Jover, A. *Lancet* 2(8103): 1305-1306; 1978.

Malignant histiocytosis (MH) was diagnosed 9 mo after the onset of systemic lupus erythematosus in a 24-yr-old man who presented with polyarthralgia, fever, and facial erythema. No immunosuppressive therapy was given before the MH developed. However, the timing invites speculation about the induction of autoimmune disorders in association with malignancy and the induction of both diseases by the same etiological agent (virus?). (4 refs)

- 79-1074 14q+ Marker Chromosome in an EBV-Genome-Negative Lymph Node Without Signs of Malignancy in a Patient with EBV-Genome-Positive Nasopharyngeal Carcinoma.** (Eng) Mitelman, F. (Dept. Clinical Genetics, Lund Univ. Hosp., S-221 85 Lund, Sweden); Klein, G.; Andersson-Anvret, M.; Forsby, N.; Johansson, B. *Int J Cancer* 23(1): 32-36; 1979.

The occurrence of a 14q+ marker chromosome in the inguinal lymph node of a patient with an Epstein-Barr virus (EBV)-genome-positive nasopharyngeal carcinoma is reported. The inguinal lymph node showed no morphological evidence of malignant lymphoma and no sign of metastatic tumor growth from the nasopharyngeal carcinoma. The lymph node was negative for EBV-determined nuclear antigen. A biopsy specimen from the nasopharyngeal tumor was found to contain 28 EBV-genome equivalents per cell; the cervical lymph node contained 19 EBV-genome equivalents per cell, while the inguinal gland did not contain detectable amounts of EBV-DNA. Chromosome analysis of 61 cells from the inguinal lymph node demonstrated that the 14q+ marker chromosome was an 8:14 translocation. This indicates that chromosome aberrations may precede histological signs of malignancy. (32 refs)

- 79-1075 Mycosis Fungoides--An Unusual Association (Letter to Editor)?** (Eng) Fraser, N. G. (Dept. Dermatology, Aberdeen Royal Infirmary, Aberdeen, Scotland); Donald, D. *Clin Exp Dermatol* 3(4): 456; 1978.

The case report of a man (48 yr old) with mycosis fungoides who, 23 yr earlier, had been treated for malignant lymphoma of the axillary lymph nodes is summarized. Recent histological review of the surgically excised lymph node specimens indicated that pleomorphic histiocytic type malignant lymphoma was present in the nodes. Skin biopsy showed a pleomorphic lymphoid cell infiltrate in the upper dermis with exocytosis and Pautrier's microabscesses in the epidermis. Therefore, the clinical and histological features suggest that the patient had developed two separate and unrelated lymphomas. The association of two unrelated lymphomas in the same patient is uncommon and has not been previously reported in mycosis fungoides. (6 refs)

- 79-1076 A Case of Eccrine Adenoma--Histological, Histochemical, and Enzyme Histochemical Studies.** (Jpn) Takematsu, H. (Dept. Dermatology, Tohoku Univ. Sch. Medicine, Sendai 980, Japan); Kato, T. *Jpn J Clin Dermatol* 32(11): 947-951; 1978.

A case of eccrine ductal adenoma in a 60-yr-old woman is reported. Histologically, the tumor tissue showed an increased amount of glycogen-containing epithelium and it was PAS-positive. There was an increased level of succinic-malate

dehydrogenase, which is characteristic of eccrine ductal adenomas. (20 refs)

- 79-1077 Multiple Familial Spiradenoma, Cutaneous Cylindroma, and Trichoepithelioma.** (Spa) Mag-nin, P. H. (Catedra de Dermatologia, Universidad Nacional de Buenos Aires, Urquiza 609, Buenos Aires, Argentina); Duhm, G.; Casas, J. G. *Med Cutan Iber Lat Am* 5(3): 179-187; 1977.

Multiple spiroadenoma, cutaneous cylindroma, plus trichoepithelioma (TE) were found in two members of a family, and a third member had multiple TE (all women, aged 19, 54, and 57 yr). There is an autosomal dominant association between multiple TE and the two other tumors. (19 refs)

- 79-1078 Juvenile Thyroid Carcinoma.** (Ita) Manetta, A. (I Divisione Chirurgica, Ospedale S. Gennaro, Naples, Italy); Cali, C.; Cevoli, S.; Mainiero, P. *Rass Int Clin Ter* 58(12): 839-846; 1978.

The occurrence of juvenile thyroid carcinoma in a 15-yr-old girl is reported, and the epidemiology and etiology of these tumors are discussed. Two years before the thyroid carcinoma was diagnosed, the patient had undergone subtotal thyroidectomy for a parenchymatous and colloid-cystic goiter. She observed the growth of a tumor several months after the operation. She subsequently underwent a second partial thyroidectomy, and the tumor was diagnosed as a follicular adenocarcinoma. The patient's history was unremarkable, but the published literature shows that 30%-40% of patients with juvenile thyroid carcinoma have been irradiated in infancy. Rats treated with thiouracil were found to develop thyroid tumors, the size of which was smaller in males than in females. Thyroiditis, especially Hashimoto's disease, is considered as a precancerous condition. (22 refs)

- 79-1079 Hyperplasia of the Adrenal Medulla.** (Ita) Scorza, R. (Istituto di Semeiotica Chirurgica, Università di Milano, Milan, Italy); Odero, A.; Giordanengo, F. *Minerva Med* 69(55): 3785-3794; 1978.

Arterial hypertension due to focal hypertrophy and hyperplasia of the adrenal medulla was found in a 28-yr-old man. A very small adenoma of the cortex was also found in the gland. The hypertension recurred after subtotal adrenalectomy, and the lesion was diagnosed as pheochromocytoma. (40 refs)

- 79-1080 Certain Aspects of Pheochromocytoma.** (Dut) van den Broek, P. J. (Afdeling Nierziekten,

Academisch Ziekenhuis, Leiden, Netherlands); de Graeff, J. *Ned Tijdschr Geneesk* 122(46): 1795-1801; 1978.

The clinical and prognostic aspects of pheochromocytoma are described on the basis of 43 new cases. They included 23 men and 20 women aged 17-70 yr. The pheochromocytoma was localized in one adrenal gland in 30 cases, was bilateral in 3, and was extraadrenal in 10 cases (paraortic in 6, thoracic in 2, and localized in the hilus of the kidney in 2). The pheochromocytoma was malignant in two cases; both patients developed lung metastases; one 0.5 and one 6 yr after surgery. (34 refs)

79-1081 A Clinicopathologic Study of 56 Cases of Intraocular Medulloepitheliomas. (Eng) Broughton, W. L. (Dept. Ophthalmology, Natl. Naval Medical Center, Bethesda, MD); Zimmerman, L. E. *Am J Ophthalmol* 85(3): 407-418; 1978.

A clinicopathologic and follow-up study was undertaken of 56 patients with intraocular medulloepithelioma. The median age at the time of initial clinical manifestation was 3.8 yr, but the median age at the time of surgery and histopathologic diagnosis was 5 yr. Pain and poor vision were the predominant symptoms, and leukocoria and a mass in the iris, anterior chamber, or ciliary body were the most frequent signs. Sixty-six percent of the medulloepitheliomas were classified as malignant. All of these had undifferentiated areas resembling retinoblastoma; 22 of 37 showed invasion of uvea, cornea, or sclera; 10 had sarcomatous components; and 16 exhibited exceptional pleomorphism or mitotic activity, or both. Seventeen of the 37 malignant tumors were teratoid. The 19 benign tumors were generally smaller and often confined to the inner surface of the ciliary body, posterior chamber, and retrolental area. These tumors were composed of sheets and cords of medullary epithelium resembling that of the embryonic retina and ciliary epithelium. Enucleation was the most frequent surgical treatment, being performed in a total of 43 cases. A diagnostic iridectomy or iridocyclectomy was performed before enucleation on eight patients who had masses in the iris or ciliary body. The most important prognostic feature was extraocular extension, which was observed in 10 cases. All four deaths due to tumor metastasis were preceded by clinically obvious orbital spread. In four additional cases with orbital involvement, the patients were lost to follow-up. It is concluded that the prognosis is worse than the results of this study indicate, especially among patients with extraocular extension. (13 refs)

79-1082 Leiomyoma of the Ciliary Body. (Eng) Vogel, M. (Univ. Eye Hosp., Gosslerstr. 12, D-3400 Gottingen, W. Germany); Spitznas, M.; Waubke, T. N. *Albrecht Von Graefes Arch Klin Ophthalmol* 209(2): 89-98; 1978.

The clinical, histological and electron microscopic features

of a ciliary body leiomyoma removed from the right eye of a 55-yr-old woman are presented. The moderately vascularized, round, lens-shaped tumor was excised completely. The retinal pigment overlying it was partly degenerated, and there was no infiltration of the adjacent sclera. The histopathologic diagnosis was leiomyoma or schwannoma. The size and shape of the cells and nuclei were variable and irregular, as shown by electron microscopy. The surface of the cells was covered by a very thick basement membrane, and the vast extracellular space between adjacent cells was filled primarily with a homogeneous electron-translucent ground substance containing striated collagen fibrils and a network of loosely arranged, fine fibrils. The electron microscopic diagnosis was smooth muscle cell tumor, with further differentiation regarding the malignancy of the tumor being impossible at this level. The differential diagnosis among amelanotic malignant melanoma, schwannoma, and neurofibroma is discussed. (7 refs)

79-1083 Metastatic Adenocarcinoma to the Anterior Uvea and Increased Carcinoembryonic Antigen Levels. (Eng) Denslow, G. T. (Dept. Ophthalmology, Univ. Kentucky Medical Center, Lexington, KY); Kielar, R. A. *Am J Ophthalmol* 85(3): 363-367; 1978.

The case report a 47-yr-old man with chronic unilateral iridocyclitis with secondary glaucoma is presented. An increased plasma carcinoembryonic antigen level (100 nanograms/ml) ultimately led to the correct diagnosis of metastatic adenocarcinoma to the anterior uvea. Although extensive clinical studies failed to demonstrate the primary tumor site, the results of histochemical staining indicate that it was in the gastrointestinal tract. (17 refs)

79-1084 Malignant Hemangioendothelioma (Wilson Jones Type)--Two Autopsy Cases. (Jpn) Kitamura, K. (Dept. Dermatology, Keio Univ. Sch. Medicine, Tokyo 160, Japan). *Jpn J Clin Dermatol* 32(11): 923-930; 1978.

Two cases of Wilson Jones-type malignant hemangioendothelioma, one in an 83-yr-old woman and one in a 77-yr-old man, are reported. In the former, the tumor developed from a small purplish growth on the head that was treated with 250-350 rads 3x/wk (total dose, 15,500 rads). Three months later, pneumothorax developed in the left and then the right lung. The tumor metastasized to the cheeks, front of the ears, and neck lymph nodes. The patient died 1 yr after diagnosis. The second patient developed a small tumor on the forehead, then a tumor at the front of the ear; both were resected. A total radiation dose of 11,200 rads was then given. However, an increasing number of tumors appeared on the face, the head, and the external auditory canal. They were treated with 200 rads/day. Subclinical lateral invasion of the tissues continued, however, and pneumothorax developed in the right

lung. The patient died from bilateral pneumonia 10 yr after diagnosis. (16 refs)

- 79-1085 Apocrine Cystadenoma.** (Jpn) Takeoka, K. (Dept. Dermatology, Kyorin Univ. Sch. Medicine, Shinkawa, Mitaka-shi, Tokyo 181, Japan); Chujoh, T.; Ishibashi, A.; Tanaka, M. *Jpn J Clin Dermatol* 32(11): 959-962; 1978.

A pea-sized swelling in front of the right ear of a 32-yr-old woman was resected and examined histologically. It had the typical characteristics of apocrine cystadenoma; ie, it was diastase-negative, PAS-positive, and colloid iron-positive, and it had lipofuscin-containing pigment granules in the epithelium. The features of this tumor are compared with those of 10 literature cases. (20 refs)

- 79-1086 Pacinian Neurofibroma (Letter to Editor).** (Eng) Webb, J. N. (Pathology Dept., Western General Hosp., Crewe Road, Edinburgh EH4 2XU, Scotland). *Histopathology* 2(6): 461; 1978.

An ultrastructural study has recently established that Pacinian neurofibromas are of nerve-sheath origin. The cell of origin is almost certainly the perineural cell, but an origin from the Pacinian corpuscle or other sensory nerve endings probably derived from cellular elements of the perineural sheath has not been ruled out. However, origin from the latter would be very difficult to prove, because the tumor would obliterate their very fine terminal axons. (no refs)

- 79-1087 Computer Tomography for Tumors of the Left Atrium.** (Ger) Lackner, K. (Radiologische Klinik, Universität Bonn, 5300 Bonn-Venusberg, W. Germany); Heuser, L.; Friedmann, G.; Thurn, P. *ROEFO* 129(6): 735-739; 1978.

The use of computer tomography (CT) in the diagnosis of cardiac tumors is illustrated by the case reports of three patients with myxomas of the left atrium. All three tumors were shown by CT as hypodense space-occupying lesions; accurate locations of the lesions were given by CT also. CT is recommended for cases of suspected heart tumors; echocardiography may give additional information on the movement of stalked tumors or thrombi. (26 refs)

- 79-1088 Cardiac Fibrosarcoma with Bone Metastases.** (Eng) Naimark, A. (Dept. Radiology, Jewish General Hosp., Montreal, Quebec, Canada); Lander, P.; Casoff, J.; Doggett, R. *J Can Assoc Radiol* 29(4): 275-276; 1978.

The third case of cardiac fibrosarcoma with bone metastases is reported. The constellation of multiple lytic bone lesions in association with unremitting pulmonary edema in a patient (a 47-yr-old man) without preexisting heart disease suggested the correct diagnosis, which was substantiated by echocardiography. (8 refs)

- 79-1089 Superficial Basal Cell Carcinoma of 32 Years' Duration.** (Eng) LoBuono, P. (Long Branch, 147 Pavilion Ave., Long Branch, NJ, 07740); Albert, J. *J Med Soc NJ* 75(13): 929-930; 1978.

A superficial basal cell carcinoma (BCC) of 32 yr duration was found incidentally in a 72-yr-old woman hospitalized for an unrelated problem. During the years of its growth, three different physicians misdiagnosed the carcinoma as eczema. Superficial spreading BCC differs clinically from other types of BCC--it usually is found on the trunk, it rarely invades underlying structures, and it is chronic. (3 refs)

- 79-1090 Adenoid Basal Cell Epithelioma Involving a Finger.** (Eng) Enna, C. D. (Clinical Branch, U.S. Public Health Service Hosp., Carville, LA). *Hand* 10(3): 309-311; 1978.

A rare case of adenoid basal cell epithelioma of the finger occurred in an 87-yr-old man who presented with a diffusely erythematous "raw" lesion of the skin overlying the dorsal aspect of the middle phalanx of the left ring finger. The lesion had increased slowly in size for 3 yr, and it showed no evidence of cellular secretory activity. Diagnosis was made upon punch biopsy. (4 refs)

- 79-1091 Subungual Squamous Cell Carcinoma.** (Eng) Attiyeh, F. F. (Dept. Surgery, Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY, 10021); Shah, J.; Booher, R. J.; Knapper, W. H. *JAMA* 241(3): 262-263; 1979.

The clinical findings, diagnosis, and therapy in 12 patients (10 men, 2 women, aged 36-80 yr, av 58 yr) presenting with subungual squamous cell carcinoma during a 27-yr period are presented, and the relevant literature is reviewed. Trauma or chronic paronychia were predisposing factors in five patients, and chronic radiation exposure or radiation therapy could have played an etiological role in another five patients. Disarticulation of the distal phalanx proved to be effective therapy in most patients. (19 refs)

- 79-1092 Multiple Bowen's Disease.** (Jpn) Ohyama, K. (Dept. Dermatology, Kumamoto Univ. Medical

Sch., 1-1-1 Honso, Kumamoto 860, Japan); Kuwahara, H.; Hamada, M. *Jpn J Clin Dermatol* 32(11): 931-938; 1978.

A 76-yr-old man was hospitalized with about 150 pea-sized to walnut-sized flat pigment moles and an egg-sized tumor in the groin. Examination of the resected groin tumor revealed Bowen's carcinoma with clumped cells and individual keratinized cells. Topical therapy with 5% 5-fluorouracil was discontinued after 10 days because of erosion of the surrounding tissues. There was no sign of metastasis at this stage. Four months later, a swelling occurred in both groins; the tumors enlarged rapidly, and the patient died from cachexia. The patient had no history of an association with arsenic. (69 refs)

79-1093 Acantholytic Squamous Cell Carcinoma Arising on Senile Keratosis. (Jpn) Kimura, K. (Div. Dermatology, Kagawa Prefectural Central Hosp., Takamatsu 760, Japan); Fujita, H. *Jpn J Clin Dermatol* 32(11): 953-958; 1978.

A brown-grey swelling on the right wrist of an 88-yr-old man was excised. Histologically, the tumor appeared to be an acantholytic squamous cell carcinoma (ASCC). There was no sign of regional lymph node involvement. The site was treated with 5-fluorouracil for 1 mo; it became eroded after 3 wk and formed epithelium after 4 wk. One year later, however, small pea-sized tumors appeared at the site. They also had typical ASCC cells. There were clumps of keratinized columnar cells, which seems to be typical of acantholysis. (31 refs)

79-1094 Epithelioid Sarcoma of Hand and Forearm. (Eng) Boyes, J. G. (1928 Randolph Rd., Charlotte, NC); Marroum, M. C. *Hand* 10(3): 302-305; 1978.

The case of a 49-yr-old woman with an epithelioid sarcoma of the hand and forearm is reported. This tumor, which has a high rate of recurrence or metastasis, occurs predominantly in male manual workers aged 20-50 yr. The lesion presents in the palm, forearm, or anterior tibial areas as an ulcerating subdermal induration or as a multinodular lesion attached to the fascia or tendon sheath. Extension occurs directly to the skin or through the lymphatics. Metastasis occurs by erosion and invasion of blood vessels to the lung lymphatics and parenchyma. (8 refs)

79-1095 Metastatic Carcinoma of the Skin--Clinicohistopathological Observations. (Jpn) Tamura, N. (Dept. Dermatology, Keio Univ. Sch. Medicine, Tokyo 160, Japan); Kitamura, K. *Jpn J Clin Dermatol* 32(11): 963-970; 1978.

Clinical and histological findings in 20 cases of metastatic skin cancer seen since 1940 are presented. The original sites

of 15 tumors were the breast (5), stomach (4), uterus (2), colon (1), rectum (1), upper jaw (1), and kidney (1); the origin of 5 was not known. There were 3 cases of differentiated adenocarcinoma, 5 cases of undifferentiated adenocarcinoma, 4 cases of squamous cell carcinoma, and 6 cases of scirrhous carcinoma, 1 case of undifferentiated carcinoma, and 1 case of renal carcinoma. Among the 13 patients for whom follow-up data were available, the av survival rate was 10.5 mo. Clinically, 9 cases developed a single skin metastasis and 11 developed multiple skin metastases. Generally, squamous cell carcinoma originated from the breast, uterus, and upper jaw and it metastasized near the original sites. On the other hand, digestive tract cancers metastasized to sites all over the body. (17 refs)

79-1096 Giant Melanin Granules in Vitiliginous Achromia with Malignant Melanoma. (Eng) Ortonne, J. P. (Clinique Dermatologique, Hôpital Edouard Herriot, F-69374 Lyon Cedex 2, France); Perrot, H. *Acta Derm Venereol (Stockh)* 58(6): 475-480; 1978.

Histological and ultrastructural examination of the normal and perilesional skin of a 68-yr-old woman with vitiliginous depigmentation associated with a metastatic malignant melanoma revealed the presence of giant melanin granules in keratinocytes and melanocytes. These pigment masses may be the remains of melanophagosomes in which the protein structure of the melanosomes had been destroyed. The numerous instances of melanosome autophagocytosis seen in the periphery of the achromic lesions appear to support this concept. (14 refs)

79-1097 Hand Metastasis from Melanoma: A Case Study. (Eng) Gelberman, R. H. (Div. Orthopaedic Surgery, Univ. California at San Diego, Univ. Hosp., 225 W. Dickinson St., San Diego, CA, 92103); Stewart, W. R.; Harrelson, J. M. *Clin Orthop* (136): 264-266; 1978.

The case of a 24-yr-old man with an early peripheral metastatic lesion from melanoma is presented. The patient presented with right thumb pain 4 yr following the removal of a pigmented lesion from his shoulder. Biopsy demonstrated cortical destruction and soft tissue invasion by malignant melanoma. The patient underwent disarticulation of the thumb, excision of the old scar from the shoulder, and excision of an sc forearm lesion. He developed right proximal humerus metastasis 5 mo later, and he currently has pulmonary and widespread osseous metastases. (22 refs)

79-1098 Placental Metastasis of Disseminated Malignant Melanoma. Report of One Case. (Por) Silveira, E. (Departamento de Clinica Medica, Universidade Estadual de Campinas, Rua Alberto de Salvo, 311, 13.100

Campinas, Sao Paulo, Brazil); de Oliveira Filho, J. A.; de Souza, S. A.; Favaro Neto, A. *J Bras Ginecol* 86(2): 39-42; 1978.

Ovarian and placental metastases of a malignant skin melanoma were found in a 34-yr-old woman during Cesarean section. The cells of the placental metastasis were found in the intervillous space. The baby is apparently normal; the lack of fetal involvement is explained by its immune defense. (10 refs)

79-1099 Basal Cell Epithelioma in a Chronic Leg Ulcer. (Eng) Burns, D. A. (Dept. Dermatology, Royal Free Hosp., Pond St., London NW3 2QG, England); Calnan, C. D. *Clin Exp Dermatol* 3(4): 443-445; 1978.

The case report of a 79-yr-old woman with a 20-yr history of leg ulceration plus basal cell epithelioma is presented. Biopsy of the elevated margin of the ulcer revealed basal cell epithelioma. Tissue from a scarred area adjacent to the ulcer and from the margin of the ulcer did not show any evidence of neoplasia. Constant irritation and chronic infection are the probable etiological factors initiating neoplastic change in stasis ulcers. However, the incidence of neoplastic change in the lesions is extremely low, compared with the numbers of long-standing leg ulcers encountered. Some cases may be missed because the appearance of the ulcer is not atypical. Biopsy of chronic stasis ulcers should be performed more frequently so that a potentially remediable situation is not neglected. (3 refs)

79-1100 Synovial Hemangioma of the Knee. Report of a Case. (Fre) Rogez, J. M. (Clinique orthopédique adulte et infantile, Hôpital Saint-Jacques, 44035 Nantes Cedex, France); Letenneur, J.; Triclot, P.; Mussini, M.; Bainvel, J. V. *J Chir (Paris)* 115(10): 545-549; 1978.

The occurrence of a synovial hemangioma of the knee, a rare benign tumor, in an 11-yr-old boy is reported. The tumor is practically always palpable and is seldom spread diffusely. Because there are few specific clinical signs, the tumor is difficult to diagnose. (22 refs)

79-1101 Chemotactic Responses of Tumor Cells to Products of Resorbing Bone. (Eng) Orr, W. (Dept. Pathology, Univ. Manitoba Health Sciences Centre, Winnipeg, Canada R3E 0Z3); Varani, J.; Gondek, M. D.; Ward, P. A.; Mundy, G. R. *Science* 203(4376): 176-179; 1979.

To explore possible mechanisms for the metastasis of malignant cells to bone, a model of tumor cell migration using Walker carcinosarcoma or malignant lymphoma cells was developed. Culture media from fetal rat long bones stimulat-

ed to undergo resorption by products of Walker carcinosarcoma cultures were tested for chemotactic activity toward tumor cells, using modified Boyden chemotaxis chambers. Media from bone cultures in which resorption had occurred attracted significantly more tumor cells ($p < 0.05$) into its membrane filters than media from untreated bones. Chemotactic activity was not detected in the supernatant fluids from devitalized bones, or in control media. Migration of tumor cells to resorbed bone media was independent of the humoral mediator of bone resorption. Bones stimulated to resorb by supernatant fluids from cultured tumor cells, parathyroid hormone, or prostaglandin E_1 all released factors that stimulated the movement of tumor cells into the membrane filters. EL-4 murine lymphoma was also attracted by media from resorbing bones. Like the Walker carcinosarcoma cells, the cells of this tumor responded to bone-derived factors regardless of the mediator of bone resorption. The findings suggest that bone contains a factor that is chemotactic for tumor cells and is released when bone is resorbed. (15 refs)

79-1102 Chondrosarcoma Developed in the Distal Phalangeal Bone of the Third Toe: A Case Report. (Eng) Miki, T. (711-18 Hikisho Nishi-machi, Osaka, Japan); Yamamuro, T.; Oka, M.; Urushidani, H.; Itokazu, M. *Clin Orthop* (136): 241-243; 1978.

A 38-yr-old woman developed a chondrosarcoma in the distal phalanx of the third toe 10 yr following fracture of the distal third and fourth toes. The toe had become enlarged 4 yr after the fracture but only became painful after a minor accident. The clinical and radiological findings suggested that the tumor may have been due to a long-term enchondroma or residual cartilaginous fracture callus that eventually underwent malignant transformation. (9 refs)

79-1103 Ewing's Sarcoma in a 13-Month-Old Boy. (Ger) Tiedjen, K. U. (Nuklearmedizinische Abteilung Elisabeth-Hospitals, 4630 Bochum, W. Germany). *ROEFO* 129(6): 798-800; 1978.

Ewing's sarcoma in a 13-mo-old boy is described. The first symptoms were pain and swelling of the lower leg. X-rays, femoral arteriography, scintigraphy (perfusion and whole-body) and, finally, biopsy were used to make the diagnosis. No evidence for metastasis has been found in the 2nd yr after therapy (amputation and polychemotherapy). (15 refs)

79-1104 An Ivory Vertebra: Monostotic Paget's Disease of Bone. (Eng) Harris, D. J. (Dept. Pathology, Princess Margaret Hosp., Univ. Toronto, Toronto, Ontario, Canada); Hons, C. B.; Fornasier, V. L. *Clin Orthop* (136): 173-175; 1978.

The case of a 30-yr-old woman with Paget's disease of the 12th thoracic vertebral body is presented. The vertebral body was uniformly radiodense but had a normal outline, indicative of ivory vertebra. Metastatic radiological survey and scintigraphic examination confirmed that the patient had monostotic involvement. (15 refs)

- 79-1105 Chondromyxoid Fibroma of Lumbar Spine.** (Eng) Mayer, B. S. (Dept. Radiology, Univ. Oregon Health Sciences Center, Veterans Admin. Hosp., Portland, OR). *J Can Assoc Radiol* 29(4): 271-272; 1978.

The first occurrence of chondromyxoid fibroma in the lumbar spine is reported. The patient, a 23-yr-old man, was referred following abnormal preemployment films of the area. Radiography revealed a well-circumscribed, expanding, cystic lesion in the spinous process of the second lumbar vertebra with no involvement of the pedicles. A thick sclerotic rim and some scalloping of the inner margins were seen. (6 refs)

- 79-1106 Suppression of Malignancy in Human Lung Cancer (A549/8) x Mouse Fibroblast (3T3-4E) Somatic Cell Hybrids.** (Eng) Carney, D. N. (NCI-Veterans Admin. Medical Oncology Branch, 50 Irving St., N.W., Ward 2CN, Room C104, Washington, DC, 20422); Edgell, C. J.; Gazdar, A. F.; Minna, J. D. *J Natl Cancer Inst* 62(2): 411-415; 1979.

The highly tumorigenic human bronchioloalveolar lung cancer cell line A549/8 and the nontumorigenic mouse fibroblast line 3T3-4E were fused through the use of polyethylene glycol 1000 and analyzed after 40-50 generations for tumorigenicity, growth in agarose, and for 20/23 human chromosomes by isoenzyme markers. A549/8 is tumorigenic in nude (nu/nu) mice, forms colonies in agarose, and is not contact-inhibited; 3T3-43 exhibits the opposite traits. Isoenzyme analysis revealed preferential segregation of human chromosomes and retention of mouse chromosomes; however, each of the 20 human chromosomes assayed was represented in at least some of the 14 hybrid clones. All 14 independent hybrid clones tested in 85 nude (nu/nu) mice by sc inoculation were nontumorigenic, indicating that the malignancy of the lung cancer cells behaved as a recessive trait. Six hybrid clones formed colonies on agarose at efficiency rates of 1%-4%, but the remainder formed no clones. These phenotypes were discordant with all human isoenzymes tested, and agarose clonability could not be related to specific human chromosomes. The nontumorigenicity of the hybrids cannot be explained by the absence of a single copy of the 20 chromosomes analyzed, but gene dosage may play a role. (36 refs)

- 79-1107 Salmonella Infection Complicating Bronchoalveolar Carcinoma.** (Eng) Safirstein, B. H. (Dept.

Pulmonary Medicine, Saint Michael's Medical Center, Newark, NJ); Ramirez, E.; Dhakhwa, R. B.; Garfield, G. *J Med Soc NJ* 75(13): 921-923; 1978.

The rare association of alveolar cell carcinoma with secondary salmonella infection, which occurred in a 27-yr-old man, is documented. The patient presented with a 3-day history of purulent yellow sputum, cough, and fever. The report also underlines the difficulty in isolating salmonella organisms from blood, sputum, and bronchoscopic washings, despite continued clinical infection. The diagnosis of both conditions was established following open lung biopsy. (7 refs)

- 79-1108 Clear-Cell Carcinoma of the Lung Metastatic to the Hamate: A Case Report.** (Eng) Nissenbaum, M. (Hand Rehabilitation Center, Ltd., 243 S. 10th St., Philadelphia, PA, 19107); Kutz, J. E.; Lister, G. D. *Clin Orthop* (134): 293-296; 1978.

The case of a 46-yr-old man with clear-cell lung carcinoma metastatic to the hamate is presented. The symptoms simulated sympathetic dystrophy, and diagnosis was delayed because of the late appearance of radiographic changes over 6 mo after symptoms appeared. Early bone scanning in patients with chronic pain may provide useful information prior to the appearance of x-ray changes. (16 refs)

- 79-1109 Glomerulonephritis as a Prodromal Symptom of Lung Cancer.** (Fre) Unger, J. (Service de Medecine, Hopital Saint-Pierre, Universite Libre de Bruxelles, 322 Rue Haute, B 1000 Brussels, Belgium); Mockel, J.; Devroede, C.; Paduart, P.; Rutsaert, J. *Nouv Presse Med* 7(43): 3937; 1978.

A case of epimembranous glomerulonephritis occurred in a 59-yr-old man who, 10 mo later, was found to have lung cancer. The patient died 5 mo later of metastases from the undifferentiated epidermoid carcinoma. Bronchogenic cancer is the visceral solid tumor most likely to be associated with epimembranous glomerulonephritis. (3 refs)

- 79-1110 Asbestosis. A Clinical Material.** (Nor) Melbostad, E. (Lungeavdelingen, Rikshospitalet, Stockholm, Norway). *Tidsskr Nor Laegeforen* 98(31): 1561-1563; 1978.

Asbestosis was diagnosed in 10 patients (9 men, 1 woman, aged 41-71 yr) who had been exposed to asbestos occupationally for 1-41 yr (av 21 yr). All patients had lung fibrosis, eight had pleural reaction, and three of them had calcified plaques. (13 refs)

- 79-1111 A Case of Primary Germ Cell Tumor of the Posterior Mediastinum with Features of Endodermal Sinus Tumor.** (Jpn) Kobayashi, M. (Dept. Surgery, Shimane Prefectural Central Hosp., Shimane, Japan); Fujino, M.; Yumoto, T. *Jpn J Thorac Surg* 131(12): 942-945; 1978.

The case of a 63-yr-old man with posterior mediastinal germ cell tumor having features of an endodermal sinus tumor is presented. Histologically, the neoplasm contained communicating cavities, lined by cuboidal or flattened cells, and papillary structures. Cylindrical epithelial structures were located around the vessels, and in cross section these structures vaguely resembled immature glomeruli. Although most other similar tumors reported in the literature were fatal, this patient has been in good health for 5 yr following surgery. Postoperatively, he received 9,000 rads to the posterior mediastinum. (9 refs)

- 79-1112 Leiomyosarcoma of the Thorax.** (Eng) Carlson, D. H. (Dept. Radiology, Newton-Wellesley Hosp., Newton Lower Falls, MA, 02162); Hanelin, J. *J Can Assoc Radiol* 29(4): 221-224; 1978.

Three cases of leiomyosarcoma of the thorax are presented: an endobronchial lesion presenting with atelectasis, a parenchymal lesion presenting as a mass, and a rare extrapleural lesion arising in the chest wall. All three patients were men (aged 34, 65, and 71 yr), and three-fourths of the literature cases are in men. Two of the patients were admitted for evaluation of abnormalities seen on routine chest radiographs. The lesions are very aggressive, and all three patients died during their first postoperative year with metastatic disease. (20 refs)

- 79-1113 Carcinoma of the Antethoracic Skin Graft Esophagus.** (Eng) Kormano, M. (Dept. Diagnostic Radiology, Univ. Hosp., SF-20520 Turku 52, Finland); Yrjana, J. *ROEFO* 129(6): 789-790; 1978.

An epidermoid carcinoma developed at the upper anastomosis of a reconstructed esophagus in a 70-yr-old woman 51 yr after the operation (for lye stricture of the esophagus). A histologic diagnosis of squamous cell carcinoma of the antethoracic skin graft was made. The etiology may be chronic irritation, since many carcinomas are related to persistent fistula. In this patient, no fistula could be demonstrated until late in the course of the disease. Contrast radiology is limited in evaluating the nature of irregularities of the esophageal wall. (9 refs)

- 79-1114 Free Intestinal Transplantation in Cervical Esophageal Carcinoma.** (Ger) Keminger, K. (I. Chi-

urgische Universitätsklinik, Alser Strasse 4, A-1097 Vienna, Austria). *Acta Chir Austriaca* 10(3): 60-66; 1978.

Ten years after replacement of a lye-damaged esophagus by a retrosternal colon segment, a 55-yr-old woman experienced difficulty in swallowing. A pavement epithelial carcinoma at the anastomosis was diagnosed by biopsy. The defect was repaired with a free-intestinal transplant. Swallowing difficulty recurred 6 mo later. Carcinoma was found deep in the neck muscles. (5 refs)

- 79-1115 Directed Cytology of the Esophagus and Stomach. A Comparison of 3 Rapid Collection Methods.** (Eng) Graham, D. Y. (Dept. Medicine, Baylor Coll. Medicine, Houston, TX, 77030); Spjut, H. J.; Estrada, R. G. *Gastrointest Endosc* 24(6): 277-280; 1978.

Three methods for collecting cytological specimens from the esophagus and stomach without prolonging the endoscopic procedure are described. One is brush cytology, and two new methods make use of the aspiration channel of Olympus endoscopes. The new methods include aspiration of exfoliated cells directly from the surface of lesions, and aspiration of material remaining within the biopsy channel after brushing and/or forceps biopsies. Salvage of material remaining within the channel provides a useful and rapid method of obtaining specimens. (13 refs)

- 79-1116 A Case of Peutz-Jeghers Syndrome.** (Pol) Szklanny, J. (Klinika Chirurgii Ogólnej, Instytut Chirurgii AM, Lodz, Poland); Zimnicki, Z.; Wasiak, J.; Modzelewski, B. *Pol Przegl Chir* 50(8): 703-705; 1978.

A case of Peutz-Jeghers syndrome with gastric polyp was diagnosed in a 25-yr-old woman who underwent surgery for intussusception of the small intestine. (10 refs)

- 79-1117 An Evaluation of Gastric Biopsy in the Diagnosis of Gastric Cancer.** (Eng) Sancho-Poch, F. J. (Dept. Gastroenterology, Hosp. Sant Cruz y San Pablo, Barcelona 25, Spain); Balanzo, J.; Ocana, J.; Presa, E.; Sala-Cladera, E.; Cusso, X.; Vilardell, F. *Gastrointest Endosc* 24(6): 281-282; 1978.

The yield of endoscopic biopsy was assessed in a consecutive series of 174 gastric cancer patients seen during 1974-1975. A correct endoscopic diagnosis was made in 157 patients, and a histological diagnosis of malignancy was obtained by endoscopic biopsy in 163 patients. Plots of the number of positive biopsy fragments against the total number of fragments secured in each case, showed that all cases in which more than eight biopsies had been carried out included at least one positive for malignancy. Probability analysis showed that

when eight fragments were taken, there was a > 99% chance of a correct diagnosis in at least one. (12 refs)

- 79-1118 Gastric Polyps and Precancerous Mucosal Changes After Partial Gastrectomy.** (Eng) Janunger, K. G. (Dept. Surgery, Univ. Hosp., Umea, Sweden); Domellof, L. *Acta Chir Scand* 144(5): 293-298; 1978.

The incidence of gastric polyps among patients who had previously undergone a Billroth I (108 patients) or Billroth II (228 patients) procedure was compared with that among 407 nonoperated controls. Among the partial gastrectomy patients, 3.6% had stump carcinoma and 8.9% had gastric polyps (28 sessile polyps and 2 pedunculated polyps). The incidence of gastric polyps in the nonoperated controls was 4.9% (18 sessile and 2 pedunculated) and the age and sex distributions were similar to those in the gastrectomy group. Repeated endoscopic check-ups were performed in 57.4% of the gastrectomy patients. The diagnostic accuracy with regard to malignancy was not entirely satisfactory. Histological examination of the surgical specimen from one of four patients with precancerous changes showed a macroscopically invisible early carcinoma. Follow-up examinations disclosed carcinoma in 3 patients and precancerous changes or adenoma in 2 patients with sessile polyps. Careful reexamination of all patients with precancerous changes and gastric polyps is recommended. (31 refs)

- 79-1119 Primary Intestinal Localization of Hodgkin's Disease. A Case Initially Diagnosed as a Benign Eosinophilic Granuloma of the Small Intestine.** (Fre) Graveleau, P. (Service de Medecine Interne, Centre Medico-Chirurgical Foch, F 92151 Suresnes, France); Perol, R.; Mornet, P.; Morin, M. *Nouv Presse Med* 7(43): 3909-3911; 1978.

The case of a 49-yr-old woman with Hodgkin's disease confined to the small intestine and mesenteric nodes for 3 yr is reported. The intestine was resected in three separate interventions. The original diagnosis of eosinophilic granuloma was changed to Hodgkin's disease only when the patient was terminal and abdominal lymph node biopsies revealed Sternberg cells. (12 refs)

- 79-1120 Incidence of Polyps of the Large Intestine in General Hospitals. Study of 2,783 Consecutive Autopsies.** (Por) Aparecido Assiz, L. (Serv. de Gastroenterol. Cir., Hosp. do Servidor Publ. Estadual Francisco Morato de Oliveira, Sao Paulo, Brazil); Habr-Gama, A.; Claudio Godoy, A.; Ferrao, S.; Mattosinho Franca, L. C.; Goffi, F. S. *AMB: Rev Assoc Med Bras* 24(7): 251-252; 1978.

The incidence of polyps of the large intestine was studied in 2,783 consecutive autopsies performed during a 12-yr period.

The incidence of polyps in the large intestine was 91/2,783 (3.2%); 53 were found in men, 38 in women. Polyps were not found in the age group 0-20 yr (450 cases). The polyp was located in the cecum in 13 cases, in the ascending colon in 11, in the transverse colon in 10, in the descending colon in 16, and in the rectum and sigmoid in 28; the localization was not recorded in 13 cases. The polyp was associated with cancer in 18 cases; the cancer was localized in the sigmoid colon in 3 cases, in the stomach in 4, in the urinary bladder in 2, in the bile ducts in 3, in the bronchi in 2, in the liver in 2, and in the pancreas and prostate in 1 case each. (11 refs)

- 79-1121 Ectopic Production of ACTH by a Primary Adenocarcinoma of the Colon.** (Eng) Stambaugh, J. E. (1210 Brace Road, Cherry Hill, NJ, 08034); Redfield, E. S. *J Med Soc NJ* 75(13): 925-926; 1978.

The ectopic ACTH syndrome was found in a 72-yr-old man being treated for adenocarcinoma of the colon with hepatic metastasis. The diagnosis of the syndrome was suggested by the sudden development of severe hypokalemic alkalosis, profound weakness, and diabetes mellitus. It was confirmed by the finding of high serum and tumor levels of ACTH (185 picograms/ml and 2,350 picograms/g, respectively). This is the first documented instance of metastatic colonic adenocarcinoma producing the ectopic ACTH syndrome. (5 refs)

- 79-1122 The Place of Radiology in Tuberous Sclerosis (Bourneville's Disease).** (Ger) Teske, H. J. (Rontgendiagnostik-Abteilung, Universitätsklinikum der Gesamthochschule Essen, Hufelandstrasse 55, 4300 Essen 1, W. Germany). *ROEFO* 129(6): 770-777; 1978.

Two women (29 and 35 yr old) with an incomplete form of tuberous sclerosis, which was accompanied by bilateral renal tumors, are described. The incomplete form of the disease is difficult to diagnose, and angiography cannot always differentiate the accompanying tumors from malignant neoplasms. Both patients also showed typical changes in the fingers and toes as well as intracerebral calcification, and in one patient the lungs were affected. (131 refs)

- 79-1123 Double Hypernephroid Carcinomas of the Kidney.** (Ger) Weiland, H. (Radiologische Klinik, St. Vincenz-Krankenhaus Limburg, Auf dem Schafsberg, 6250 Limburg, W. Germany). *ROEFO* 129(6): 794-795; 1978.

A rare case of one-sided, double hypernephroid carcinoma of the kidney occurred in a 65-yr-old woman. Angiography showed two spherical, well-separated tumors (5 and 5.5 cm diameter) in the left kidney. The vessels of both tumors had the criteria of malignancy. The final diagnosis was based on histological findings. (3 refs)

- 79-1124 Ultrastructural Features in Normal and Hyperplastic Postmenopausal Endometrium.** (Eng) Deligdisch, L. (Mount Sinai Hosp., Fifth Ave. and 100th St., New York, NY, 10029); Yedwab, G.; Persitz, A.; David, M. P. *Acta Obstet Gynecol Scand* 57(5): 439-452; 1978.

The ultrastructural features of samples of normal and hyperplastic postmenopausal endometrium (PMEM) were compared. Of the total seven samples, four were diagnosed as adenomatous hyperplasia (2 of which were atypical) and 3 as normal PMEM. The most striking ultrastructural features of the hyperplastic endometrium were numerous nucleoli, deep nuclear membrane infoldings, an increased nucleocytoplasmic ratio, a prominent and enlarged rough endoplasmic reticulum closely associated with mitochondria and the nuclear membrane, abundant free ribosomes, and marked network microfilaments. In the two cases of atypical adenomatous hyperplasia, the protruded intraglandular proliferating epithelial cells exhibited more atypical features than the epithelial cells of the glandular lining, suggesting a more advanced degree of anaplastic change. The characteristic features of the normal PMEM were a paucity and random distribution of the cytoplasmic organelles and the presence of large cytoplasmic vacuoles and short, blunt microvilli. Secretory vacuoles opening into the lumen of the gland were found in one case of cystic atrophy of a normal PMEM. Collagenization was found in the stroma of both groups, although predominantly in the normal PMEM. In two cases of adenomatous hyperplasia, stromal cells with a vacuolar cytoplasm were found. The significance of these findings, as related to their importance as precursor stages of endometrial cancer (adenomatous and atypical adenomatous hyperplasia), as involutional manifestations (normal PMEM), and as related to the absence of cyclic activity (both groups) is briefly discussed. (11 refs)

- 79-1125 Classification and Stages of Carcinoma of the Uterine Cervix.** (Ita) Ferraris, G. (II Clinica Ostetrica e Ginecologica, Università di Torino, Via Ventimiglia, 3, Turin, Italy). *Minerva Med* 69(54): 3679-3686; 1978.

The 1976 F.I.G.O. (International Federation of Gynecology and Obstetrics) classification of carcinoma of the uterine cervix is presented. Carcinoma in situ and intraepithelial carcinoma are classified as Stage 0. In Stage I, the carcinoma is strictly limited to the cervix. Microinvasive carcinoma (initial stroma invasion) is classified as Stage IA and all other cases of Stage I as IB. In Stage II, the carcinoma is extended to the vagina but not to its inferior third nor to the pelvic wall. Unlike Stage IIB, there is no parametrial involvement in IIA. Involvement of the pelvic wall is the criterion for Stage III. Invasion of the vesical or rectal mucosa is seen in Stage IV. (no refs)

- 79-1126 The Significance of Lymphography for the Prognosis of Cervical Carcinoma.** (Ger) Schon-

dorf, N. (Universitäts-Frauenklinik, 6650 Homburg Saar, W. Germany); Amengual, M.; Dietz, R. *ROEFO* 129(6): 778-781; 1978.

The lymphograms (LG's) of 92 cervical carcinoma patients were compared with the histological findings in 45 of these patients. Histology confirmed the LG findings in 36 cases; the LG's were false-positive in 5 cases and false-negative in 4. During a 3- to 5-yr follow-up, the carcinoma progressed in 16/30 of the positive-LG patients vs 7/62 of those with normal LG's. The use of lymphography is recommended as a guide to the prognosis of patients with cervical carcinoma. (27 refs)

- 79-1127 Cervical Ectropion: Its Relationship with Carcinoma In Situ of the Uterine Cervix.** (Spa) Gaitan Galarza, V. (Laboratorio de Anatomia Patologica y Citologia Exfoliativa, LAPCE, Av. Oaxaca 96, Mexico 7, D.F., Mexico); Schulz Contreras, M.; Miranda Sanchez, A. *Patol Quir Citol Esfoliativa* 3(3): 143-151; 1977.

The relationship between cervical ectropion and carcinoma in situ of the uterine cervix was studied in 311 women (aged 15-80 yr) who underwent colposcopy, exfoliative cytology, and cervical biopsy. Ectropion was found in 141 cases (45%); all these patients were aged 15-60 yr; the incidence of ectropion was 100% in the age bracket 15-20 yr, 76% in the age bracket 21-30 yr, and lower in the higher age groups. The ectropion was periorificial in 118 cases, marginal in the others. Papillary ectropion was found in 125 cases, ectropion with regenerating epithelium in 10, polypoid ectropion in 4, and flat ectropion in 2. Intraepithelial carcinoma was found in 5/141 patients with ectropion, and in 2/170 patients without ectropion. The cytology revealed metaplasia in 87/141 patients with ectropion, and in 40/170 patients without ectropion. The findings indicate that metaplasia occurs preferably in ectropion, which is the most frequent premalignant lesion. (19 refs)

- 79-1128 Metamutation: A New Histogenetic Theory of Carcinoma In Situ of the Cervix.** (Eng) Duarte, E. (Rua Barao de Lucena, 95 Rio de Janeiro, RJ, Brazil). *J Bras Ginecol* 86(2): 19-28; 1978.

On the basis of histological observations of 418 patients with carcinoma in situ of the cervix from 1952 to 1977, a new histogenetic theory ("metamutation" theory) for the development of cervical carcinoma was conceived. According to this theory, the columnar cells of the endocervical epithelium undergo a metaplastic epidermoid transformation and after that a carcinomatous mutation, giving rise to carcinoma in situ of the cervix without going through dysplastic phases. (7 refs)

- 79-1129 Breast Biopsy at the Hospital dos Servidores do Estado (HSE). Results of 2,025 Examinations**

During the 1963-1972 Period. (Por) Toleda Piza, B. (Servico de Cirurgia Geral, Hospital dos Servidores do Estado, Rio de Janeiro, Brazil); Torres, E.; Lopes Chaves, L. C.; dos Santos, G. G.; Tanaka, E. *Rev Med HSE (Hosp Servidores Estado)* 29(4): 215-222; 1977.

Breast biopsy, performed in 2,025 women with mastopathy, revealed dysplasia in 1,010 cases, benign tumors in 344, malignant tumors in 329, various mastopathies in 288, and inflammation in 54. (5 refs)

79-1130 The Significance of Ferritin in Malignant Diseases. (Eng) Giler, S. (Dept. Surgery B, Rogoff-Wellcome Medical Res. Inst., Beilinson Medical Center, Petah Tikva, Israel); Moroz, C. *Biomedicine* 28(4): 203-206; 1978.

A subpopulation of circulating T lymphocytes bearing surface ferritin was recently found in patients with breast cancer and untreated Hodgkin's disease, but not in normal subjects or patients with benign breast disease. The appearance of this subpopulation in the circulation is an early manifestation of neoplastic disease, and its identification may provide a tool of potential diagnostic and prognostic importance in the management of breast cancer and Hodgkin's disease. (43 refs)

79-1131 Meconium Periorchitis. (Ger) Senff, A. (Institut für Pathologie der Universität Zurich, Universitätsspital, CH-8091 Zurich, Switzerland); Hedinger, C. *Z Kinderchir* 25(2): 125-135; 1978.

Two cases of meconium periorchitis are reported, as illustrations of the difficulty of diagnosing this condition. Both patients presented with palpable intrascrotal masses during the first 10 days of life. Both underwent complete removal of both testes because a malignant tumor was diagnosed. The correct diagnoses for both cases was reached only after further histological study. (27 refs)

- 79-1132 Sacrococcygeal Teratoma--Diagnosis and Therapy.** (Ger) Willital, G. H. (Kinderchirurgie, Chirurgische Univ.-Klinik Erlangen, Maximiliansplatz, 8520 Erlangen, W. Germany); Meier, H.; Schneider, H. *Z Kinderchir* 25(2): 113-125; 1978.

Data on sacrococcygeal teratomas are reviewed. The incidence is 1/30,000-40,000 births, and 75% of the patients are female. Only 9% have malignant tumors within the first 8 wk of life, but after that time the incidence of malignancy increases 50%-70%. (23 refs)

- 79-1133 Survey of Mortality among Employees Engaged in the Manufacture of Styrene and Polystyrene at the BASF Ludwigshafen Works.** (Eng) Frentzel-Beyme, R. (Deutsches Krebsforschungszentrum, Heidelberg, W. Germany); Thiess, A. M.; Wieland, R. *Scand J Work Environ Health* 4(Suppl. 2): 231-239; 1978.

The 1956-1976 mortality experience among persons employed at a West German styrene (SR)- and polystyrene-manufacturing plant for >1 mo since 1931 was surveyed. The cohort comprised 1,960 SR workers exposed for a total of 20,138 person-yr. There were 74 deaths, 12 of which were due to malignant neoplasms. The proportion of deaths due to malignant neoplasms was less in the cohort (14.9%) than in the entire population of West Germany (18.5%). Percentages of deaths due to neoplasms of the lymphatic and hematogenic systems were very similar in the two groups. When the cohort was subdivided into groups with 5-9, 10-14, or >15 yr of exposure, no increase in total mortality or mortality from malignant tumors occurred with increasing exposure time. Thus, it appears that prolonged exposure to SR is not a cancer hazard. (7 refs)

- 79-1134 Burkitt's Lymphoma of the Spinal Cord.** (Eng) Olumide, A. A. (Neurosurgery Unit, Dept. Surgery, University Coll. Hosp., Ibadan, Nigeria); Adeboye, A. *Trop Geogr Med* 30(2): 215-218; 1978.

The clinical pattern of Burkitt's lymphoma of the spinal cord seen in 20 patients during 1971-1976 is reported. Peak incidence was at 10-12 yr of age, and the major symptoms were paraplegia and various degrees of lower limb paresis, impaired sensation, and double incontinence. Hepatosplenomegaly was observed in 11 patients. The cerebrospinal fluid had elevated protein levels, and most patients were anemic on admission. (12 refs)

- 79-1135 Nasal Cancer Associated with Occupational Exposure to Organic Dust.** (Eng) Engzell, U. (Dept. Otorhinolaryngology, Huddinge Sjukhus, S-14185 Huddinge, Sweden); Englund, A.; Westerholm, P. *Acta Otolaryngol (Stockh)* 86(5/6): 437-442; 1978.

Records of the Swedish National Board of Health and Welfare were studied to determine whether the development of carcinoma of the nose and paranasal sinuses is related to occupational exposure to dust. Patients with nasal and paranasal sinus cancer were divided into one of two groups: 36 men and 10 women who presented with adenocarcinoma between 1961 and 1971 and 127 men and 85 women who presented with squamous cell or poorly differentiated carcinoma between 1965 and 1971. Fifty-three percent of the men in the first group had been employed as joiners, and at least 12 of these men had been cabinet makers. Three persons had been employed in the flour industry. The length of occupational exposure to dust among the nine joiners in whom this was established was 25 yr or more. No occupation predominated among the 62 men who responded to a questionnaire in the group with squamous cell or poorly differentiated carcinoma. The investigation shows that the bulk of men with adenocarcinoma of the nose and paranasal sinuses had been exposed to wood dust. (9 refs)

- 79-1136 Cancer Risk in Extensive Ulcerative Colitis.** (Eng) Kewenter, J. (Dept. Surgery III, Sahlgren's Hosp., S-413 45 Goteborg, Sweden); Ahlman, H.; Hulten, L. *Ann Surg* 188(6): 824-828; 1978.

Two hundred thirty-four patients who had developed extensive ulcerative colitis between 1951 and 1974 were followed until December 1975, and the cumulative risk of developing cancer of the large bowel was estimated. Fifteen patients with 17 large bowel carcinomas were found: 5 in the colon ascendens, 5 in the transversum, 3 in the sigmoid colon, and 4 in the rectum. The duration of ulcerative colitis in these patients was 7-44 yr. The expected number of colorectal carcinomas in a matched reference group was 0.49. The cumulative incidence of carcinoma 25 yr after the onset of colitis for the whole group of patients was 34%; it was 43% for those who developed the disease before 25 yr of age. These results suggest that elective surgery for patients with extensive colitis of 10-15 yr duration should be carefully considered. (19 refs)

- 79-1137 Clinical Features, Mortality and Survival of Patients with Asbestosis.** (Eng) Huuskonen, M. S. (Inst. Occupational Health, Haartmaninkatu 1, SF-00290

Helsinki 29, Finland). *Scand J Work Environ Health* 4(4): 265-274; 1978.

The clinical features, mortality, and survival rate of 202 patients (174 men, 28 women) diagnosed as having asbestosis between 1964 and 1976 at the Finnish Institute for Occupational Health were determined. Of the 202 patients, 133 had a clinical reexamination. Major characteristics included breathlessness in 118, persistent sputum in 95, crepitations in 77, and finger clubbing in 43. The underlying cause of death of the 62 patients who died before the study began were asbestosis (26), lung cancer (20), other malignancies (4), and other causes (12). Lung cancer was peripheral in 17 cases and central in 3. Peripheral cancers were located in the upper lobe in 11 cases and in the lower lobe in 6 cases. Nine of the lung cancer patients were insulators, 6 were asbestos quarry workers, 4 worked in a factory manufacturing asbestos cement products, and 1 was a carpenter who had been exposed indirectly. The number of deaths among the male patients was 56, compared to the expected number of 23.4 estimated from the death rates among men of the same age in the Finnish general population. The respective figures for lung cancer were 19 observed and 2.1 expected. No excess mortality was found for other cancers. Among the men with asbestosis, the life expectancy was shorter for smokers than for non- and ex-smokers. (30 refs)

79-1138 Excess Risk of Lymphomas, Leukemia and Myeloma in Patients with Rheumatoid Arthritis. (Eng) Isomaki, H. A. (Rheumatism Foundation Hosp., 18120 Heinola 12, Finland); Hakulinen, T.; Joutsenlahti, U. *J Chronic Dis* 31(11): 691-696; 1978.

The incidence of malignancies among 11,483 men and 34,618 women with rheumatoid arthritis was investigated. A total of 407 neoplasms was observed in men; this was significantly higher ($p < 0.01$) than the expected number (354.1). The incidence of leukemia, lymphoma, myeloma, and respiratory cancer was significantly higher ($p < 0.001$) than in the general male population. In women, the incidence of malignancies was similar to the expected incidence. The incidence of lymphoma, myeloma, and Hodgkin's disease was significantly higher than expected ($p < 0.001$), while the incidence of stomach cancer was significantly lower ($p < 0.05$). The expected number of all lymphatic system cancers in both sexes was 59.6, compared with the 130 cases observed ($p < 0.001$). (19 refs)

79-1139 Metabolic Epidemiology of Large Bowel Cancer. Fecal Bulk and Constituents of High-Risk North American and Low-Risk Finnish Population. (Eng) Reddy, B. S. (Naylor Dana Inst., Valhalla, NY, 10595); Hedges, A. R.; Laakso, K.; Wynder, E. L. *Cancer* 42(6): 2832-2838; 1978.

The dietary pattern and fecal constituents of two populations with the greatest contrast in colon cancer incidence were studied. The first group comprised 15 healthy middle-aged men from the low-risk population in Kuopio (KP), Finland, and the second 20 age-matched healthy men from a high-risk population in the New York (NY) Metropolitan area. The av daily intake of dietary fat was 96.6 and 99.6 g/day and that of protein was 94.8 and 86.7 g/day in KP and NY, respectively. However, the sources of fat were different, a greater portion coming from dairy products in KP and from meat in NY. The KP group consumed more whole-grain bread and cereals and less green vegetables and fruits than the NY men. The frequency of bowel movements was higher and the daily total stool out-put and fecal fiber excretion were greater in KP. The concentration of fecal secondary bile acids and bacterial β -glucuronidase activity was significantly lower in KP, but the total daily excretion of these constituents was the same in both groups. The daily fecal excretion of bacterial nuclear dehydrogenase activity and of a neutral sterols was higher in KP, but the concentration of these constituents was the same in the two groups. The most likely factor contributing to the low risk of colon cancer in Finland, in spite of a high dietary intake of fat, appears to be the high intake of dietary fiber. This leads to an increase in stool bulk, which dilutes promoters such as bile acids and yet to be identified carcinogens. (29 refs)

79-1140 Flexible Sigmoidoscopy: A Potential Advance in Cancer Control. (Eng) Crespi, M. (Cancer Detection Center, Istituto Regina Elena, Viale Regina Elena 291, Rome, Italy); Casale, V.; Grassi, A. *Gastrointest Endosc* 24(6): 291-292; 1978.

The potential for a higher yield of neoplastic lesions with the use of flexible fiberoptic sigmoidoscopy is pointed out. The mean level reached in 468 subjects was 63 cm, and the av time required per exam was 6 min. Of the 56 polypoid lesions found, 30 were above 25 cm, and 19 of these were neoplastic. Fifteen of 26 polypoid lesions found below 25 cm were neoplastic. Three cancers were found; one, at 40 cm, would not have been detected by rigid sigmoidoscopy. (11 refs)

79-1141 Diffuse Pleural Mesothelioma in Trieste. A Survey Based on Autopsy Cases. (Eng) Bianchi, C. (Istituto di Anatomia e Istologia Patologica, Ospedale Maggiore, Via Stuparich, 1, 34100 Trieste, Italy); Grandi, G.; Di Bonito, L. *Tumori* 64(6): 565-570; 1978.

A survey of diffuse pleural mesothelioma in Trieste, Italy, was made based on autopsies conducted between 1971 and 1977. Definite diffuse pleural mesothelioma was diagnosed in 23 men and 3 women ranging in age from 52 to 81 yr. The interval between first symptoms and death ranged from 4 mo to 5 yr. A clinical diagnosis of pleural mesothelioma was made in 15 cases; a tumor (pulmonary, thoracic, or undeter-

LIBRARY U. OF I. URBANA - CHAMPAIGN

mined) was diagnosed in 6, but in 5 cases no tumor had been suspected or recognized. Mesothelioma affected the left pleura in 13 cases, the right pleura in 12, and was bilateral in 1. The most frequent site of metastasis was the lungs, followed by the mediastinal lymph nodes and liver. There was coinvolvement of the pericardium in six cases. Malignancy was histologically obvious in all cases. A history of smoking habits was obtained in 23 cases and a detailed occupational history was available in 25 cases. Fourteen patients were smokers and 22 had been occupationally exposed to asbestos for 2-43 yr. The av interval between first exposure and death was 44 yr. The intensity of exposure was moderate in all cases, and asbestos bodies were found in the lungs of 20 patients. The incidence of diffuse pleural mesothelioma in Trieste is relatively high compared with that in other countries and in other parts of Italy. (12 refs)

- 79-1142 Concentration and Distribution of Heavy Metals in Nasal Mucosa of Nickel-Exposed Workers and of Controls, Studied with Atomic Absorption Spectrophotometric Analysis and with Timm's Sulphide Silver Method.** (Eng) Torjussen, W. (Sentralsykehuset, Kristiansand, 4601 Kristiansand, Norway); Haug, F. M.; Andersen, I. *Acta Otolaryngol (Stockh)* 86(5/6): 449-463; 1978.

The nickel, copper, cobalt, zinc, and iron content of biopsy specimens from the nasal mucosa of 30 nickel-exposed individuals and 6 controls was determined by atomic absorption spectrophotometry. In addition, the possibility that the sulfide staining pattern is affected by variations in these concentrations was investigated. Although the mean concentration of nickel in the nickel-exposed subjects was greater than that in controls, this difference was not statistically significant. However, the nickel concentration in the nasal mucosa of the subjects who worked in the roasting and smelting department was significantly higher ($p < 0.02$) than that in workers in other departments. No consistent differences were found in the histochemical pattern between biopsies with high and low nickel concentrations or any of the other metals. Some difference in epithelial types between specimens from the nickel-exposed group and the control group was seen, but the staining pattern was similar for corresponding epithelial types in the two groups. Two nasal carcinomas from nickel workers were unstained with the sulfide staining method. (25 refs)

- 79-1143 Association of Kaposi's Sarcoma and Prior Immunosuppressive Therapy. A 5-Year Material of Kaposi's Sarcoma in Norway.** (Eng) Klepp, O. (Det Norske Radiumhospital, Montebello, Oslo 3, Norway); Dahl, O.; Stenwig, J. T. *Cancer* 42(6): 2626-2630; 1978.

To determine the possible role of prior immunosuppressive (IS) treatment in the development of Kaposi's sarcoma (KS), a retrospective study was made of 53 histologically diagnosed

cases of KS reported to The Cancer Registry of Norway over a 5-yr period. Four cases were excluded from the material because further information contradicted the diagnosis of KS. Of the remaining 49 cases, information concerning treatment received before the development of KS was obtained for 41. Six of the 41 patients developed KS during systemic treatment with corticosteroids; 2/6 cases had also taken azathioprine. The time from the start of medication to the first sign of KS was 1, 4, 7, and 7 mo, and 7 and 8 yr, respectively. None of the patients had undergone renal transplantation. One additional patient had received radiotherapy (4,000 rads) for a malignant lymphoma prior to the development of KS. In a control group of 242 consecutive patients hospitalized because of basal cell carcinoma of the skin, none had used systemic corticosteroid or cytotoxic drugs. Case reports of the seven patients who developed KS after IS therapy are presented. Previous studies have shown that patients treated with IS drugs after renal transplantation seem to have a higher than expected risk of developing KS. This study indicates that there is also an association between prior IS therapy and development of KS in patients who have not received a renal transplant. (28 refs)

- 79-1144 Polyps of the Large Intestine in Northern Norway.** (Eng) Eide, T. J. (Dept. Pathology, Univ. Hosp., 9012 Tromsø, Norway); Stalsberg, H. *Cancer* 42(6): 2839-2848; 1978.

Autopsy results on the incidence of large intestinal polyps in northern Norway are reported. Adenomas (AD's) of the colon and rectum were present in 68/171 men and 36/109 women > 20 yr of age. The frequency of AD's increased with age in both sexes. Hyperplastic polyps were found in 55/280 cases, and there was no variation in frequency with sex or age. Before age 65, most AD's were located in the distal half of the large intestine in both sexes. After 65 yr in men and 75 yr in women, the preferred site shifted to the proximal half. The av size and grade of adenomatous atypia increased with age, but no significant difference in grade of atypia was found between the proximal and distal halves. The occurrence of AD's was not associated with any of the common chronic diseases thought to be related to a western-style diet or to malignant or benign neoplasms in other organs. A significant association was found between the occurrence of AD and high body wt. These findings support the view that AD's are important precursors for carcinomas of the large intestine. The change in subsite distribution of AD's with age corresponds to a similar, but later change in the distribution of carcinomas, and the higher incidence of carcinomas in older men is in accordance with an earlier rise in the prevalence of AD's in men than in women. (42 refs)

- 79-1145 Fecal Bile Acids in Two Japanese Populations with Different Colon Cancer Risks.** (Eng) Mow-er, H. F. (Dept. Biochemistry and Biophysics, John A. Burns

Sch. Medicine, Univ. Hawaii, Honolulu, HI, 96822); Ray, R. M.; Shoff, R.; Stemmermann, G. N.; Nomura, A.; Glober, G. A.; Kamiyama, S.; Shimada, A.; Yamakawa, H. *Cancer Res* 39(2, Part 1): 328-331; 1979.

The fecal bile acid patterns in two ethnically similar but geographically separate groups with markedly different colon cancer risk patterns were compared to examine the hypothesis that persons with higher levels of total and degraded fecal bile acids are at greater risk of colon cancer. Stool specimens were collected from 122 Japanese subjects living in Akita, Japan (JJ: the lower risk group), and from 247 Japanese subjects living in Hawaii (HJ: the higher risk group) and analyzed by gas chromatography. A diet-recall questionnaire designed to quantitate recent intakes of specific Western or Japanese food items was administered, and certain physiological data were obtained. HJ men were significantly taller and heavier and had greater hematocrit values than did JJ men who, on the other hand, had higher levels of systolic blood pressure. HJ women had slightly greater hematocrit values than did JJ women. With respect to Western foods, HJ men and women ate significantly more beef, bacon, lettuce, celery, and coffee than their counterparts in Japan, whereas JJ men and women ate significantly more dried fish, soybean curd, rice, pickled Chinese cabbage, pickled turnip, pickled plum, and genmai cha tea. More persons in Japan than in Hawaii had measureable levels of lithocholic, chenodeoxycholic, and ursodeoxycholic acids. HJ men and women had higher mean values for deoxycholic and cholic acids and for three unidentified degraded bile acids, whereas the JJ subjects had higher values for one unknown degraded bile acid. The results neither disprove nor support a major role for bile acids in the etiology of large-bowel cancer. It is possible that the higher frequency of colon cancer in the HJ population is due to an as yet unidentified carcinogen in human fecal specimens. (20 refs)

- 79-1146** Incidence of Leukemia in Atomic Bomb Survivors Belonging to a Fixed Cohort in Hiroshima and Nagasaki, 1950-71: Radiation Dose, Years after Exposure, Age at Exposure, and Type of Leukemia. (Eng) Ichimaru, M. (Dept. Hematology, Atomic Disease Inst., Nagasaki Univ. Sch. Medicine, Nagasaki, Japan); Ishimaru, T.; Belsky, J. L. *J Radiat Res (Tokyo)* 19(3): 262-282; 1978.

The leukemogenic effect of atomic radiation in atomic bomb survivors was examined in relation to age at the time of the bomb (ATB), latent period, and type of leukemia for the period 1950-1971. Confirmed cases of leukemia (136 cases) in the Leukemia Registry at the Atomic Bomb Casualty Commission, a fixed cohort of 109,000 subjects, and dose estimates based on the simple sum of gamma and neutron doses (tentative 1965 total dose) provided the basis for the analysis. The latent period was divided into three segments: 5-10, 10-15, and 15-26 yr after exposure. The larger the exposure dose and the younger the age ATB, the greater was the effect in the early period and the more rapid the decline in risk in subse-

quent years. In the oldest group, ≥ 45 ATB, the increase in risk appeared later and was sustained during 1960-1971. Chronic granulocytic leukemia contributed substantially to the total leukemogenic effect initially, but made little contribution after 1955. Age ATB played an important role in relation to latency period and type of leukemia. The onset of acute leukemia tended to be earlier in those who were young ATB than in those who were older. The effect of atomic radiation on the incidence of leukemia in atomic survivors is now greatly reduced and is continuing to decline, but the incidence in 1966-1971 was still greater than expected, especially in Hiroshima. In Nagasaki, no case of leukemia was reported among the high-dose subjects from July 1966 through 1971. (38 refs)

- 79-1147** Carcinogenic Hazard from Natural Background Radiation in Japan. (Eng) Ujeno, Y. (Dept. Experimental Radiology, Faculty Medicine, Kyoto Univ., Sakyo-ku, Kyoto 606, Japan). *J Radiat Res (Tokyo)* 19(3): 205-212; 1978.

The relationship between natural background radiation and death from cancer in 329 cities and counties in Japan was analyzed with respect to published radiation surveys and epidemiological data. The max radiation dose observed was 159.2 mR/yr and the minimum dose was 39.4 mR/yr. The incidence of male and female deaths from stomach cancer and male deaths from rectal cancer increased with increasing natural background radiation dose. Mortality from other types of cancer (esophagus, large intestine, pancreas, lung, breast, and uterus) did not show such a positive correlation. (13 refs)

- 79-1148** Relation of Radiation to Gastric Carcinoma Observed in Autopsy Cases in a Fixed Population, Hiroshima and Nagasaki, 1961-74. (Eng) Yamamoto, T. (Dept. Pathology, Radiation Effects Res. Foundation, Hiroshima 730, Japan); Shimizu, Y. *J Radiat Res (Tokyo)* 19(3): 213-227; 1978.

The relation of atomic bomb radiation to 535 cases of gastric carcinoma among 4,694 deaths occurring in a fixed population of atomic bomb survivors in Hiroshima and Nagasaki who were autopsied between 1961 and 1974 was examined. The proportion of autopsy-diagnosed gastric carcinoma cases tended to be high in the high-dose group, especially in Nagasaki, but it could not be concluded that there is a relation between gastric carcinoma and radiation in this study. There were no significant differences in the histologic type of gastric carcinoma according to radiation dose. The degree of extension of tumor cells into the gastric wall and the degree of metastasis to the lymph nodes were increased in the high-dose group. (15 refs)

- 79-1149 Gastric Cancer in Colombia. IV. Nitrite and Other Ions in Gastric Contents of Residents from a High-Risk Region.** (Eng) Tannenbaum, S. R. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Moran, D.; Rand, W.; Cuello, C.; Correa, P. *J Natl Cancer Inst* 62(1): 9-12; 1979.

The gastric juice of two groups of subjects from a region of high gastric cancer risk in southern Colombia was analyzed for nitrate, nitrite, thiocyanate, chloride, and pH. Group 1 comprised 55 subjects with previously undefined gastric pathology, and Group 2 comprised 18 subjects for whom gastric biopsy data were available (4 intestinal metaplasia, 7 chronic atrophic gastritis, 6 superficial gastritis, 10 necrosis of neck glands, 1 normal; some subjects had multiple pathologies). The nitrite level of many Group 1 members was several orders of magnitude higher than those reported previously; however, Group 1 samples were thawed and refrozen, and these levels may not be accurate. Although Group 2 levels were somewhat lower than those of Group 1, they were still 10 to 100 times higher than those reported previously. The patients could be broken down into two subgroups, those with gastric pH < 5 or > 5, respectively. In individuals with pH > 5 (28 Group 1 subjects, 9 Group 2 subjects) nitrate and nitrite contents were related linearly; nitrite was significantly higher in both Group 1 (90 times) and Group 2 (20 times) members of this subgroup. No correlation between pH, thiocyanate, and/or chloride and the other measured parameters was noted, and there was no variation of Zn, Ca, Cu, K, Na, Mg, or Fe ions between the high and low nitrate groups. The only Group 2 subject with a low nitrite content and pH > 5 was the only one with a normal mucosa. This is the first report of patients with gastric pathology related to a precancerous state showing high levels of a putative carcinogen precursor, and it supports the hypothesis of the intragastric bacterial reduction of nitrate to nitrite with concomitant formation of carcinogenic N-nitroso compounds. (15 refs)

- 79-1150 Gastric Secretion in Individuals from Regions with Different Stomach Cancer Morbidity.** (Rus) Il'enkova, M. K. (Dept. Epidemiology Malignant Tumors, Cancer Res. Center, Moscow, USSR). *Lab Delo* (11): 668-671; 1978.

To evaluate the possible association between anacid gastritis and cancer of the stomach, gastric juice acidity was studied in individuals from regions with a high and low incidence of stomach cancer. It was found that in regions with a high incidence of stomach cancer, most of the population had hypoacidity of the gastric juice, but in regions with a low incidence of stomach cancer, most of the individuals had normal acidity or hyperacidity of the gastric juice. (10 refs)

- 79-1151 Geographical Distribution of Malignant Tumors of the Larynx in Georgian SSR.** (Rus)

Mgaloblishvili, G. N. (Dept. Otorhinolaryngology, Cancer Res. Center, Tbilisi, USSR); Dzhordzhadze, N. A.; Gogeliani, N. K.; Gobronidze, I. A.; Ebraldidze, D. B. *Vestn Otorinolaringol* (6): 77; 1978.

An attempt was made to determine the geographical distribution of malignant tumors of the larynx in Georgian SSR (USSR) and to evaluate the role of environmental factors of laryngeal cancer morbidity. Of 136 patients, 92 had cancer of the nasopharynx, 30 had cancer of the oropharynx, and 14 had cancer of the laryngopharynx. There was a significant association between the nasopharyngeal cancers and alcohol consumption and exposure to dust, smoke, and bordeaux mixture (fungicide made by reaction of copper sulfate, lime, and water). (no refs)

- 79-1152 Non-fibrous Mineral Dusts and Malignant Tumors: An Epidemiological Study of Mortality.** (Eng) Katsnelson, B. A. (Sverdlovsk Inst. Industrial Hygiene and Occupational Diseases, Repin Str. 2, 620014 Sverdlovsk, USSR); Mokronosova, K. A. *J Occup Med* 21(1): 15-20; 1979.

Mortality due to malignant tumors associated with nonfibrous mineral dusts in the workplace was analyzed epidemiologically by relating the the number of cancer deaths registered at five companies during a 21- to 27-yr span to the number of man-years of work for all employees during the same period. The companies comprised a plant producing silica firebricks, two plants producing aluminosilicate firebricks, a gold mine, and a company for mining, grinding, and processing talc. Death rates were compared with age-rates in a control population. The observed death rate for gastric and lung cancer and tumors of all sites was significantly greater than that expected for both men and women at the talc plant, leading to the conclusion that talc dust is a carcinogen. In industries connected with silica dust, the relative risk of death from lung and gastric cancer and other malignant tumors was enhanced considerably for men but to a much lesser degree and not in all occupations for women. This indicates that silica-containing dusts only potentiate the action of some other carcinogen(s) with which men are in contact much more than women. The data on smoking habits among men and women at two of the companies suggest that the polycyclic aromatic hydrocarbons in tobacco smoke are the carcinogenic factor in these cases. The data also indicate that silicosis apparently predisposes to the development of malignant tumors. (35 refs)

- 79-1153 Relative Genealogic Incidence of Certain "Civilization Diseases" in a Geriatric Population Versus Pregeriatric Groups.** (Eng) Zdichynec, B. (Internal Disease Div., Regional Inst. Natl. Health, Hosp. and Polyclinic, 39464 Pocatky, Czechoslovakia); Stransky, P.;

Hartmann, M.; Holas, V.; Konrad, J.; Hogen, J.; Svatos, Z.; Sabl, J. *J Am Geriatr Soc* 26(12): 534-539; 1978.

The incidence of "civilization diseases" (including malignant tumors) among persons aged 70-105 yr was determined and compared with the incidence in men aged <40 with myocardial infarction and in women and men aged <60 with stroke. The incidence of malignant tumors was relatively lower in men and women aged 90-105 than in those aged 70-79 and 80-89, but the differences were not significant. Genealogic differences in the incidence of malignant tumors were not pronounced. (16 refs)

- 79-1154 Correlation Between Tuberculosis and Lung Cancer. A Regression Analysis.** (Cze) Simecek, C. (Klinika tuberkulozy a respiracnich nemoci, FVL KU, Lesni 59, 312 12 Plzen, Czechoslovakia); Simeckova, B. *Stud Pneumol Phthisiol Cech* 38(8): 518-521; 1978.

The correlation between lung cancer incidence and pulmonary tuberculosis was studied in various districts of West Bohemia in 1977. A correlation coefficient of 0.849 and a linear regression equation (cancer incidence = $30.4 + 0.637$ tuberculosis incidence) were calculated. The close correlation cannot be explained by differences in the age of the population ($r = 0.535$) or by differences in the quality of health service, because districts serviced by the same phthisiological department are interspersed among districts with high and low incidence. The findings indicate that the lesions caused by tuberculosis are a significant factor influencing lung cancer incidence. (10 refs)

- 79-1155 Neoplasms in Tasmanian Devils (*Sarcophilus harrisii*).** (Eng) Griner, L. A. (Pathology Dept., Zoological Society San Diego, P.O. Box 551, San Diego, CA, 92112). *J Natl Cancer Inst* 62(3): 589-595; 1979.

The 50% incidence of spontaneous neoplasms and preneoplastic hyperplasia in 18 necropsied Tasmanian devils at one zoo is believed to be unusually high for any mammalian species. The occurrence of multiple concomitant tumors in 6/9 animals makes the incidence even more remarkable. With the exception of one leiomyoma and one lymphosarcoma, all tumors were of epithelial origin. Six of 10 females and 3/8 males had neoplasms. The case reports of the affected animals are presented. (9 refs.)

- 79-1156 Mesothelioma after Crocidolite Exposure During Gas Mask Manufacture.** (Eng) McDonald, A. D. (Dept. Epidemiology and Health, McGill Univ., Montreal, Canada); McDonald, J. C. *Environ Res* 17(3): 340-346; 1978.

The pattern of mortality among 199 Canadians who were occupationally exposed to crocidolite between 1939 and 1942 and who were subsequently traced to the end of 1975 is described. Of a total of 56 deaths in this cohort, 23 were from malignant disease, including 9 from mesothelioma and 8 from lung cancer. Six of the nine mesothelioma cases involved the peritoneum. The duration of exposure to crocidolite among the mesothelioma cases varied from 4 mo to 3 yr, and the latency period to death was ≤ 36 yr from the first exposure. Two additional cases of mesothelioma were uncovered in another study of the employees of one of the three factories surveyed in this study. Four individuals in the present study died of pneumoconiosis. Comparison of the crocidolite-exposed workers with a cohort of chrysotile miners and millers showed that mesothelioma was 60-fold more frequent and lung cancer was twice as frequent in the crocidolite cohort, that the proportion of deaths from other malignant diseases was similar in the two cohorts, and that only 1/11 mesotheliomas in the chrysotile cohort involved the peritoneum. The continued use of crocidolite would appear difficult to justify except under the strictest possible control. (11 refs)

- 79-1157 Epidemiology of Dysplasia and Carcinoma In Situ of the Uterine Cervix.** (Spa) Valdivia Ponce, E. (Servicio de Oncologia Ginecologica, Hosp. Central No 2 del Seg. Social del Peru, Lima, Peru); Nunez Vidallon, R.; Garcia La Madrid, M.; Vigil, R. C.; Hiromoto, T.; Campos Rivera, A. *Ginecol Obstet (Lima)* 22(1): 11-21; 1976.

The incidence of dysplasia and carcinoma in situ of the uterine cervix was studied in 97,996 cytological tests during 15-yr period in Peru. Carcinoma in situ was diagnosed in 128 cases, carcinoma Stage Ia in 35, Stage Ib in 27, Stage II in 45, Stage III in 19, and Stage IV in 13. Cervical dysplasia was found in 60 cases; the dysplasia was mild in 5 cases, moderate in 36, and severe in 19. The median age of these 60 patients was 36.5 yr (33.66 in mild dysplasia, 37.83 yr in moderate dysplasia, and 36.58 yr in severe dysplasia). Fifty-five patients were married; age at the time of first intercourse was 15-24 yr in 45 cases. The median number of children per patient was 3.61. Five patients with dysplasia subsequently developed carcinoma in situ and/or microinvasive carcinoma of the cervix. The findings suggest that cervical dysplasia and carcinoma in situ can be precursors of invasive growth. (10 refs)

- 79-1158 Nine Years Screening for Cervical Cancer: Influence on Incidence and Mortality.** (Eng) Mobius, G. (Dept. Pathology, District Hosp. Schwerin, Schwerin, E. Germany); Geiling, J. *Cancer Cytol* 18(2): 13-17; 1978.

The morbidity and mortality experience of women undergoing cytologic screening for cervical cancer between 1967 and 1976 in the district of Schwerin, East Germany (population,

600,000), is reported. The number of women examined increased from 3,000 in 1967 to 47,000 in 1972 to 60,000 in 1976. The number of positive cytological findings increased sharply from 1967 to 1972, presumably due to a "catching-up" effect, and it fluctuated between 4% and 8%. This constitutes the prevalence rate. After 1972, the exams consisted of an increasing number of reexaminations, and thus the prevalence rate was replaced by the incidence rate, which leveled to 3.5%-3.2% during 1974-1976. The rapid increase in the number of carcinomas in situ from 1967 to 1972 (from 59 to 382) was followed, in spite of marked increases in the number of cytological exams, by a decrease to 163 in 1977. The total number of invasive carcinomas dropped from 137 in 1970 to 85 in 1977. In addition, the ratio of invasive carcinomas to carcinomas in situ decreased significantly over the study period. The av age at diagnosis for patients with carcinoma in situ was 39-40 yr, for those with microcarcinoma 33-52 yr, and for those with invasive carcinoma 51-58 yr. Whereas the annual number of deaths due to breast cancer (which has a similar incidence rate) fluctuated only slightly in the district from 1969 to 1976, that due to carcinoma of the cervix uteri decreased from a max of 80 in 1969 to 39 in 1976. (no refs)

- 79-1159 Diagnosis of Stomach Cancer--A Retrospective Analysis.** (Ger) Grungreiff, K. (Medizinische Akademie Magdeburg, Medizinische Klinik, Leipziger Strasse 44, DDR-301 Magdeburg, E. Germany); Hofs, R.; Kleine, F. D.; Hofs, T.; Kleine, S. *Dtsch Gesundheitsw* 33(46): 2168-2171; 1978.

Gastroscopic and x-ray findings were compared retrospectively for 323 patients, 65 of whom were found to have stomach cancer. The correct diagnosis was given by x-rays in 69.3% of the cases and by gastroscopy in 90.7%. Previous stomach resection, pernicious anemia, stomach ulcers, and polyps are considered special indications for gastroscopy. (46 refs)

- 79-1160 Epidemiological Factors Related to the Malignant Neoplasms in Ataxia-Telangiectasia Families.** (Eng) Daly, M. B. (Biological Sciences Res. Center, Univ. North Carolina, Chapel Hill, NC, 27514); Swift, M. *J Chronic Dis* 31(9/10): 625-634; 1978.

Twenty-seven ataxia-telangiectasia (AT) families were examined for selected epidemiological characteristics to see if risk factors other than the AT gene could explain the increase in deaths from cancer in general and from carcinomas of the biliary system, ovary, or stomach in particular. Demographic, social, and medical factors associated with these cancers could not explain their increased number or early age of onset. The results support a genetic basis for the increased susceptibility of AT heterozygotes to malignant neoplasms. (42 refs)

- 79-1161 Increase in Cancer of the Corpus Uteri in the San Francisco-Oakland Standard Metropolitan Statistical Area, 1960-75.** (Eng) Austin, D. F. (San Francisco Bay Area Resource Cancer Epidemiology, State California Dept. Health, 2151 Berkeley Way, Berkeley, CA, 94704); Roe, K. M. *J Natl Cancer Inst* 62(1): 13-16; 1979.

Data collected by the Resource for Cancer Epidemiology concerning the incidence of carcinoma of the corpus uteri (CCU) in women of the San Francisco-Oakland standard metropolitan statistical area were analyzed. The age-adjusted incidence rate of invasive CCU among white women increased from 26.3 to 47.5/100,000 between 1969 and 1975, an increase of 81%. This increase was limited to women > 50 yr of age and to invasive cancers of the endometrial lining, and it correlated with the increased affluence within this age group. The increase was noted throughout the five-county reporting area; in Alameda County, the av annual incidence of invasive CCU in the 50- to 74-yr age group tripled between 1960 and 1975. There were no increases in sarcomas, which occur in the myometrium. Based on the number of cases for which stage information was available (23%-52% of total), the distribution of stage of invasive CCU remained relatively stable between 1969 and 1975. Possible spurious causes of the increase, such as changing diagnostic criteria, better case finding, or better reporting, were examined and ruled out. The increased incidence in invasive CCU is attributed to postmenopausal estrogen-replacement therapy. (10 refs)

- 79-1162 Endometrial Cancer and Estrogen Use: Report of a Large Case-Control Study.** (Eng) Antunes, C. M. (Dept. Epidemiology, Johns Hopkins Univ. Sch. Hygiene and Public Health, Baltimore, MD); Stolley, P. D.; Rosenshein, N. B.; Davies, J. L.; Tonascia, J. A.; Brown, C.; Burnett, L.; Rutledge, A.; Pokempner, M.; Garcia, R. *N Engl J Med* 300(1): 9-13; 1979.

A case-control study was conducted of the relation between estrogen use and endometrial cancer (EC). The study population consisted of 451 patients diagnosed from 1973 through 1977 and 888 controls. The overall risk of EC was six-fold for estrogen users compared to nonusers; the relative risk was 2.0 for short-term users (< 1 yr) and 15 for long-term users (> 5 yr). Increased risk was associated with estrogen use for all histologic grades of the tumor. The risk of advanced-stage carcinoma was four-fold for estrogen users; however, the 95% confidence interval was 1.0 to 22, so that this issue is still unsettled. There was increased risk of EC with both diethylstilbestrol and conjugated estrogens, and the risk associated with cyclic use was as great as that for continuous use. The lag time between onset of postmenopausal bleeding and consultation with a physician did not vary significantly between users and nonusers. None of the patients who received estrogens had had them prescribed for the treatment of abnormal bleeding, an early sign of EC. This contradicts the speculation that the association between EC and estrogen use can be explained by swifter diagnosis for estrogen users

or treatment of early symptoms of the tumor with estrogen. (10 refs)

- 79-1163 Smoking and Health: The Association Between Smoking Behaviour, Total Mortality, and Cardiorespiratory Disease in West Central Scotland.** (Eng) Hawthorne, V. M. (Dept. Epidemiology, Univ. Michigan, Ann Arbor, MI, 48109); Fry, J. S. *J Epidemiol Commun Health* 32(4): 260-266; 1978.

In three separate surveys of the relationship between smoking and total mortality in west central Scotland, in which 18,786 people were screened between 1965 and 1975, the most marked association for any cause of death was for lung cancer. In men, current smokers suffered 88 deaths/5,944 at risk, with an estimated risk about 30 times higher than that of never smokers, who suffered 1 death/2,147 at risk. (18 refs)

- 79-1164 Mortality Experience of Styrene-Polystyrene Polymerization Workers. Initial Findings.** (Eng) Nicholson, W. J. (Environmental Sciences Lab., Dept. Community Medicine, Mount Sinai Sch. Medicine, New York, NY); Selikoff, I. J.; Seidman, H. *Scand J Work Environ Health* 4(Suppl. 2): 247-252; 1978.

A survey was made of the mortality experience of 560 subjects with ≥ 5 yr continuous employment as of 1 May 1960 at a styrene production and polymerization plant. At this plant, workers were exposed to several materials, including styrene, benzene, and ethylbenzene. The cohort was followed prospectively from 1 May 1960 or upon attainment of 10 yr of employment through 31 December 1975. The expected mortality rates were calculated with a modern life table analysis and data on the mortality experience of the general population of the US. There were 83 observed deaths vs 106.41 expected; this deficit may be a result of the "healthy worker effect". No patterns were noted when mortality experience was analyzed by extent of exposure; ie, when maintenance and production workers were compared with utility and service workers. One death was directly attributable to leukemia and one to lymphoma; a third death was accompanied by leukemia. A review of 361 additional death certificates of workers employed 6 mo or more at the plant revealed five additional cases of leukemia and four of lymphoma. Although these figures are suggestive of an excess risk, the small numbers and limited follow-up time do not provide definitive information on risk of death from leukemia and lymphoma at this plant. (6 refs)

- 79-1165 Mortality Experience of 50 Workers with Occupational Exposures to the Products of Coal Hydrogenation Processes.** (Eng) Palmer, A. (SRI International, Center Occupational and Environmental Safety Health, 333

Ravenswood Ave., Menlo Park, CA, 94025). *J Occup Med* 21(1): 41-44; 1979.

The mortality experience of coal hydrogenation plant workers diagnosed with skin cancer (10) or precancerous lesions (40) during 1955-1959 was determined, and information was collected on malignancies present at the time of death. Five of the workers had died from noncancerous causes, 16 had retired, 28 were still working, and 1 was lost to follow-up. No attempt was made to pursue the health history of each worker exhaustively, but this survey did reveal that one retired worker with precancerous lesions was currently ill with Parkinson's disease and cancer of the prostate, and one retired worker with cancerous skin lesions had lung cancer. Because of the small number of workers in the cohort and the few deaths that occurred, the data were not analyzed statistically, but apparently there is no increase in death due to systemic cancers as a result of heavy occupational exposure to high boiling oils containing polycyclic hydrocarbons, coal tar, and pitch. (8 refs)

- 79-1166 Genealogy of Cancer in a Family.** (Eng) Blatter, W. A. (Environmental Epidemiology Branch, NIH, NCI, 3C 18 Landow Bldg., Bethesda, MD, 20014); McGuire, D. B.; Mulvihill, J. J.; Lampkin, B. C.; Hananian, J.; Fraumeni, J. F. *JAMA* 241(3): 259-261; 1979.

The occurrence of cancer in the family of a boy with osteogenic sarcoma was traced. A younger brother of the proband developed acute lymphoblastic leukemia and another brother developed bilateral malignant neurilemoma. A family history going back to 1850 identified cancers in all four ancestral lines of the proband. The paternal grandmother lineage showed a concentration of seven family members affected by cancers of the bone, soft tissue, nervous tissue, breast, and bone marrow. The constellation of tumors in this family appears to fall into a recently described syndrome of multiple cancers affecting children and adults. The distribution of tumors in this and other families with this syndrome suggests an autosomal dominant mode of inheritance, with incomplete penetrance suggested by skipped generations. In some members of the present family, the genetic predisposition may have interacted with environmental determinants to produce particular tumors. (12 refs)

- 79-1167 Geographic Cluster Indices for Disease Mappings.** (Eng) Roegner, R. H. (Emory Univ., Atlanta, GA, 30322). *Diss Abstr Int B* 39(7): 3408B-3409B; 1979. (no refs)

- 79-1168 Risk of Lymphoma after Cardiac Transplantation (Letter to Editor).** (Eng) Penn, I. (Dept.

Surgery, Univ. Colorado Medical Center, Denver, CO, 80262). *Lancet* 2(8104/8105): 1385; 1978.

The increased risk of developing lymphomas was compared in cardiac and renal transplant recipients. Both groups developed lymphomas within remarkably short intervals following transplantation (av of 20 and 27 mo, respectively), and the tumors showed a predilection for the CNS in these patients compared with the general population. (5 refs)

- 79-1169 Breast-Cancer Incidence and Mortality Rates in Different Countries in Relation to Known Risk Factors and Dietary Practices.** (Eng) Gray, G. E. (Dept. Community and Family Medicine, Univ. Southern California Sch. Medicine, Los Angeles, CA); Pike, M. C.; Henderson, B. E. *Br J Cancer* 39(1): 1-7; 1979.

Breast cancer incidence and mortality rates in 34 countries were examined in relation to height, wt, age at menarche, and diet. Height and wt were correlated with total fat consumption and animal protein consumption; age at menarche was correlated with total fat, animal protein, meat, and egg consumption. Breast cancer mortality rates were most highly correlated with total fat and incidence rates were most highly correlated with animal protein. Although there were positive correlations between the three anthropometric variables and breast cancer rates, the effects of the dietary variables remained even after adjusting for height, wt, and menarche. Thus, while diet may indirectly affect breast cancer rates via its effect on height, wt, and age at menarche, it may have direct effects as well. (41 refs)

- 79-1170 Breast Cancer Risk Factors Among Screening Program Participants.** (Eng) Brinton, L. A. (Environmental Epidemiology Branch, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD, 20014); Wilimas, R. R.; Hoover, R. N.; Stegens, N. L.; Feinleib, M.; Fraumeni, J. F. *J Natl Cancer Inst* 62(1): 37-43; 1979.

To examine whether the usual risk indicators for breast cancer apply to individuals participating in screening programs, data were obtained by mailed questionnaires from 405 breast cancer patients identified during the first 2 yr of operation of the Breast Cancer Detection Demonstration Project and from a sample of 1,156 normal screenees. The breast cancer patients and controls did not differ significantly with regard to age or center. A higher proportion of the patients were single, separated, divorced, or widowed, whereas more of the controls were married. The risk of breast cancer was inversely related to the age at menarche. Parity, which was highly correlated with age at birth of the first child, was correlated with a decreased risk of breast cancer. Women with a surgical menopause at ages 45 to 49 yr were at a significantly increased risk relative to women with natural menopause at the same ages. Late age at menopause was correlated with a rela-

tively high risk, and the relative risk increased with cumulative years of menstruation. Family history of breast cancer was a statistically significant risk indicator, and relative risk increased with wt. Among women who had undergone natural menopause, an excess risk was present among those using birth control pills in the presence of breast cancer risk indicators. (25 refs)

- 79-1171 Plasma Oestradiol and Progesterone Levels in Women with Varying Degrees of Risk of Breast Cancer.** (Eng) Bulbrook, R. D. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Moore, J. W.; Clark, G. M.; Wang, D. Y.; Tong, D.; Hayward, J. L. *Eur J Cancer* 14(12): 1369-1375; 1978.

Plasma estradiol and progesterone levels were determined in 5,000 pre- and postmenopausal women and correlated with the risk of developing breast cancer. Increased risk of breast cancer in premenopausal women correlated with subnormal plasma progesterone values (< 3 nanograms/ml) in the luteal phase of the menstrual cycle and a subnormal excretion of urinary androgen metabolites. Plasma estradiol values did not vary with risk. In postmenopausal women, plasma estradiol and progesterone levels were not related to risk. One striking finding was that premenopausal women with a subnormal excretion of urinary etiocholanolone were predominantly those who, 5 yr later, had a luteal deficiency, which implies that the abnormality is not sporadic but may occur in most menstrual cycles in women at high risk. It also indicates that measurement of plasma progesterone and of urinary androgen metabolites may give the same prognostic information. It may be possible to check this should a sufficient number of the 5,000 volunteers eventually develop breast cancer. If a deficiency in the luteal phase secretion of progesterone proves to be an important determinant of risk, the correlation of such an abnormality might be possible. (16 refs)

- 79-1172 Urethral Tumours.** (Eng) Stewart, P. A. (Dept. Urology, General Infirmary, Great George St., Leeds 1, England); Anderson, C. K.; Williams, R. E.; Clark, P. B. *Br J Urol* 50(7): 583-585; 1978.

During the last 10 yr, 33/660 male patients undergoing follow-up for multiple superficial tumors of the bladder developed urethral tumors, an incidence of 5%. There was no evidence that the tumors had been disseminated by repeated endoscopic diathermy. Thirty-two patients had papillary carcinoma of the bladder and one had a single, solid, superficial carcinoma of the trigone. (1 ref)

- 79-1173 The Redundant Factor Method and Bladder Cancer Mortality.** (Eng) Barrett, J. C. (Dept. Medical Statistics and Epidemiology, London Sch. Hygiene

and Tropical Medicine, Keppel St., London WC1E 7HT, England). *J Epidemiol Commun Health* 32(4): 314-316; 1978.

It is sometimes advantageous to include all three factors of age, cohort of birth, and time (year of death) in a mortality analysis, although one of them may appear to be redundant. Use of cohorts is essential for diseases with long induction periods, such as cancer, in which a decline in cohort factors may reflect a progressive environmental diminution of a carcinogen. On the other hand, year of death may indicate a change in the accuracy or extent of coverage of death certification, affecting all age groups and occurring in a particular year, or the introduction of more effective treatment or a screening program. Both types of influences may be acting at once making it desirable to include all three factors. The problem of arbitrary linear trends contained in the solution, caused by the redundancy, can be circumvented by restricting the interpretation to those features that are free of linear trend; ie, by considering the points at which relatively large changes of slope occur. This method was applied to data on bladder cancer mortality in England and Wales during 1951-1970. The model was statistically acceptable. In this population time factors were all close to zero. The male cohort with the peak rate (born 1901) was one involved in the armed forces during World War I, and the nitrites from their large intake of tinned meats may have been a causative factor. It is more difficult to account for the peak in women born around 1920. (10 refs)

- 79-1174 Malignant Tumors in a Region of Endemic Nephropathy.** (Rus) Stoichev, I. I. (Inst. Oncology, Sofia, Bulgaria); Stoianov, I. S.; Petkova-Bocharova, T. K.; Chernozemski, I. N.; Nikolov, I. G. *Vopr Onkol* 24(12): 55-61; 1978.

Cancer morbidity and mortality indices were determined in a region of endemic nephropathy in Bulgaria. Between 1965 and 1974, 27 villages (7,399 men, 7,333 women) were examined. A total number of 657 cancer cases were recorded: the cumulative morbidity index (per 100,000) was 266.72 for men and 238.71 for women (compared with 159.45 and 165.66, respectively, among the population of a control, nonendemic region). The increase in cancer incidence was due primarily to the increased incidence of cancer of the urinary bladder (35.05 among men and 16.12 among women, vs 7.17 and 1.97, respectively, in controls) and renal pelvis (21.98 and 28.08, vs 0.61 and 4.04 in controls). (15 refs)

- 79-1175 Incidence of Mortality due to Malignant Skin Melanoma.** (Swe) Mattsson, B. (Radiumhemmet, Karolinska sjukhuset, S-104 01 Stockholm, Sweden). *Lakartidningen* 75(49): 4594-4595; 1978.

The incidence of malignant skin melanoma increased significantly in Swedish men and women alike during 1960-1972,

but the mortality rate increased significantly in men only. Although the incidence is somewhat higher in women than in men, the mortality has always been higher in men. (no refs)

- 79-1176 Opium and Oesophageal Cancer in Iran (Letter to Editor).** (Eng) Kmet, J. (9 Japljeva, 61000 Ljubljana, Yugoslavia). *Lancet* 2(8104/8105): 1371-1372; 1978.

Evidence is adduced to show that opium use is not a likely etiological factor in the prevalence of esophageal cancer in the Turkomen region of northern Iran. A normal or high occurrence of opium habits in other regions of Iran does not correlate positively with the incidence of esophageal cancer. Nutritional and immunogenetic components of this disease should be explored, and simple hypotheses regarding a genetic predisposition should not be overlooked. (1 ref)

- 79-1177 Epidemiology of Cancer of the Stomach, Gallbladder and Biliary Tract, Pancreas, and Small Intestine in Chile.** (Spa) Csendes, A. (Departamento de Cirugia, Facultad de Medicina Santiago Norte, Universidad de Chile, Santiago de Chile, Chile); Medina, E.; Braghetto, I. *Rev Med Chil* 105(12): 884-887; 1977.

Mortality due to digestive tract cancer was studied in Chile during 1971-1974. The mortality rate (per 100,000 inhabitants) was 6.7 in men and 3.6 in women for esophageal cancer, 2.5 in men and 7.1 in women for gallbladder and bile duct cancer, 3 in men and 3.1 in women for pancreatic cancer, and 0.1 in both sexes for cancer of the small intestine. - 79-1178 Nine Cases of Hepatic Carcinoma in Young Patients Born and Living in the Village of Aldea la Espinilla, Rio Hondo, Zacapa, Guatemala. Multi-Factor Theory on the Genesis of Epidemic Hepatic Carcinoma: Genetic Factor, Alcoholism and Cirrhosis.** (Spa) Morales Sandoval, J. (Sala Medicina de Hombres, Hospital Regional de Zacapa, Zacapa, Guatemala); Paiz Calderon, N.; de Cordon, N.; Humberto Oliva, O.; Cordon Rubio, L.; Pernigotto, A.; Ruiz A., D. A.; Rivas O., B. C.; Morales Barrios, J.; Gonzalez Sehaw, R.; Rosal, J. E.; Molina N., M. *Nueve Casos de Hepatocarcinoma*: 79 pp.; 1978.

Nine young inhabitants (6 men and boys and 3 girls and women, aged 9-19 yr, median age 15.03 yr) of the village of Aldea la Espinilla, Rio Hondo, Guatemala (population: 332) died of hepatoma during the period from October 1966 to January 1978. The mortality is significantly higher than the av. The investigation of the socioeconomic and hygienic conditions suggests the involvement of the following etiological factors: genetic factor (consanguinity), alcoholism, and liver cirrhosis (partly related to alcoholism). Further studies will

be necessary to elucidate firmly the etiological factors in this epidemic of hepatoma. (9 refs)

cancers. Lymphomas occur frequently in cats and are believed to be due to viral infections. (3 refs)

79-1181 **Aplastic Carcinoma in Diabetic Mice: Hyperglycemia-suppressed Proliferation Rate and Insulin Synthesis by Tumor Cells.** (Eng) Pavelic, K. (Dept. Experimental Biology and Medicine, "Rugjer Boskovic" Inst., P.O. Box 1016, 41001 Zagreb, Bijenicka c. 54, Croatia, Yugoslavia). *J Natl Cancer Inst* 62(1): 139-141; 1979.

The growth of a successively transplanted aplastic carcinoma was studied in diabetic and normoinsulinemic, hyperglycemic male CBA/H mice. The animals were divided into three experimental groups: mice with alloxan-induced diabetes, normal mice in which daily ip glucose administration caused severe hyperglycemia, and mice treated daily with glucose + 8 IU insulin. All mice were inoculated im with 1×10^6 tumor cells. Tumor cell suspensions from tumor bearers (first generation tumors) were injected into similarly treated mice to produce second-generation tumors. The procedure was repeated to produce subsequent tumor generations. Although the rate of tumor growth was originally suppressed in diabetic mice, it increased with each subsequent transplantation. The mean tumor wt and immunologically reactive insulin level also increased, whereas mean survival time and serum glucose level progressively decreased. In contrast, tumor growth was suppressed by hyperglycemia. The wt of the first-generation tumor in hyperglycemic mice was approx half that found in control mice with normal levels, and successive transplantation into other hyperglycemic mice did not result in enhanced tumor proliferation. The insulin level was considerably below normal in all nondiabetic animals with tumors independent of glucose administration, but when insulin was injected into hyperglycemic tumor bearers, there were no differences in mean survival time or tumor wt from normoglycemic tumor-bearing mice. The enhanced proliferation of aplastic carcinoma in diabetic mice was caused by de novo insulin synthesis, probably by the tumor cells themselves. (12 refs)

79-1182 **Low-Density Lipoprotein (LDL) Receptor Activity in Human Acute Myelogenous Leukemia Cells.** (Eng) Ho, Y. K. (Dept. Molecular Genetics, Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX, 75235); Smith, R. G.; Brown, M. S.; Goldstein, J. L. *Blood* 52(6): 1099-1114; 1978.

The receptor mediated uptake of low-density lipoprotein (LDL) was measured in cells of patients with different forms of leukemia. The rate of receptor-mediated uptake and high-affinity degradation of ^{125}I -labeled LDL was 3- to 100-fold higher in blood mononuclear cells from 7 patients

with acute myelogenous leukemia (AML) than in cells from 18 healthy subjects and 21 patients with acute and chronic lymphocytic leukemias, infectious mononucleosis, and non-hematologic malignancies. The rate of cholesterol (CE) synthesis from ^{14}C -acetate was also higher (2- to 30-fold) in the AML cells. The total rate of CE input (ie, the sum of LDL-derived and endogenously synthesized CE) was, on the av, ninefold higher in the AML cells than in mononuclear cells from normal subjects. In both the normal and AML cells, >90% of the CE input was derived from receptor-mediated degradation of LDL and <10% from CE synthesized within the cell. Despite the higher input of CE in the AML cells, their content of CE, as measured by the CE:protein ratio, was 50% lower than that in normal mononuclear cells. These data indicate that the turnover of cellular CE is more rapid in AML cells than in normal mononuclear cells. This enhanced turnover might be due to a more rapid rate of utilization of CE for cellular growth or to a more rapid efflux of cellular CE. The resultant depletion of cellular CE elicits both a higher LDL receptor activity and a higher rate of CE synthesis in these leukemic cells. (31 refs)

79-1183 **Suppression by Potassium Thiocyanate of Preneoplastic Development of Mammary Glands in Female Mice.** (Eng) Nagasawa, H. (Pharmacology Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Yanai, R.; Nakajima, Y. *IRCS Med Sci (Cancer)* 6(11): 450; 1978.

To help elucidate thyroid function in mammary tumorigenesis, the effects of potassium thiocyanate (KSCN, 0.1% or 0.3% in the drinking water for 5 or 12 wk) on the development of hyperplastic alveolar nodules (HAN) in female SHN mice and the development of pregnancy-dependent mammary tumors (PDMT) in female GR/A mice were determined. Compared with untreated controls, the number of HAN was significantly reduced in KSCN-treated mice. HAN size did not differ between groups and there was no difference in number of HAN between the 0.1% and 0.3% KSCN groups. Body wt gain was somewhat retarded in the 0.3% KSCN group. The incidence of PDMT was also significantly reduced by KSCN treatment, and av PDMT size was larger in controls than in treated mice. The number of PDMT per mouse, the percentage of mice becoming pregnant, and litter size did not differ significantly between groups. The results indicate that KSCN-induced hypothyroidism suppresses the preneoplastic development of the mammary glands in mice

without seriously affecting normal physiological function. (3 refs)

- 79-1184** Pyrimidine (3'-5') Purine Base Sequence Preference for Intercalation into RNAs (Meeting Abstract). (Eng) Broyde, S. (Biology Dept., New York Univ., New York, NY, 10003); Hingerty, B. *Biophys J* 25(2, part 2): 221a; 1979. (1 ref)

- 79-1185** In Vitro Mutagenesis of a Circular DNA Molecule by Using Synthetic Restriction Sites. (Eng) Heffron, F. (Dept. Biochemistry and Biophysics, Univ. California, San Francisco, CA, 94143); So, M.; McCarthy, B. J. *Proc Natl Acad Sci USA* 75(12): 6012-6016; 1978.

A technique for the in vitro mutagenesis of a circular DNA molecule is described in which synthetic oligodeoxynucleotides are used as mutagens encoding a restriction endonuclease recognition site. The circular plasmid DNA is linearized by nuclease treatment, ligated to the oligomer, treated with the cognate restriction endonuclease to generate overlapping single-stranded DNA tails, and resealed. A new circular plasmid DNA into which a single new restriction site has been randomly inserted is produced. The technique allows large numbers of mutants to be isolated at defined sites that are readily localized on the physical map through restriction endonuclease mapping. Rearrangements such as duplications and deletions can be engineered at will by using the added restriction sites. This technique was used to produce a fine-structure map of the ColE1 derivative RSF1050, 60% of which is a transposable DNA sequence encoding the TEM β -lactamase (Tn3). Most mutations within Tn3 abolished transposition, but mutations mapping within a narrow region of Tn3 resulted in an increased frequency of Tn3 transposition. This technique has numerous applications, such as inserting additional amino acid sequences to alter protein structure, inserting stop codons to determine reading frame, or in DNA sequencing. (35 refs)

- 79-1186** Mechanisms of Carcinogenesis Associated with DNA Repair. (Rus) Sasukhina, G. P. (Inst. General Genetics, Moscow, USSR). *Arkhh Patol* 40(10): 79-83; 1978.

Current data on the association between malignant transformation and DNA repair activity are summarized. A deficiency of the early stages of DNA repair was detected in the cells

of patients with hereditary diseases such as xeroderma pigmentosum, Fanconi's anemia, ataxia telangiectasia, Bloom's syndrome, and Down's syndrome. These diseases are characterized by an increased frequency of malignant transformation. In vitro experiments showed that various physical and chemical carcinogens do not induce unscheduled DNA synthesis in the cells of these patients. (24 refs)

- 79-1187** Multiple Pathways of Intrareplication (Postreplication) Repair in *E. coli* K-12 (Meeting Abstract). (Eng) Rothman, R. H. (Dept. Biology, Brookhaven Natl. Lab., Upton, NY, 11973); Clark, A. J. *Biophys J* 25(2, part 2): 156a; 1979. (3 refs)

- 79-1188** Improvement in the Sensitivity of DNA Polymerase I-Deficient *Escherichia coli* for Detecting Mutagens and Carcinogens. (Eng) Venturini, S. (Inst. Microbiology, Univ. Trieste, Trieste, Italy); Monti-Bragadin, C. *Appl Environ Microbiol* 36(6): 794-797; 1978.

The sensitivity of *Escherichia coli* strains lacking DNA polymerase I activity to the antibacterial activity of mutagens and carcinogens was increased if the strain also carried a *lexA* mutation and/or the R391 plasmid. The effects of the *lexA* mutation and plasmid appeared to be additive. The differential sensitivity of this altered strain could be adapted as a preliminary screening test for mutagens and potential carcinogens. (17 refs)

- 79-1189** Adenosine Deaminase, Terminal Deoxynucleotidyl Transferase (TdT), and Cell Surface Markers in Childhood Acute Leukemia. (Eng) Coleman, M. S. (Dept. Biochemistry, Univ. Kentucky Coll. Medicine, Lexington, KY, 40506); Greenwood, M. F.; Hutton, J. J.; Holland, P.; Lampkin, B.; Krill, C.; Kastelic, J. E. *Blood* 52(6): 1125-1131; 1978.

A systematic study of 26 children with acute leukemia indicated that measurements of adenosine deaminase and terminal deoxynucleotidyl transferase distinguish biochemical subtypes of acute lymphoid leukemia and that they complement measurements of cell-surface markers. (29 refs)

- 79-1190 "Spontaneous" Neoplastic Transformation In Vitro of Epithelial Cell Strains of Rat Liver: Cytology, Growth and Enzymatic Activities.** (Eng) Morel-Chany, E. (Institut de Recherches Scientifiques sur le Cancer, B.P. No. 8, 94800 Villejuif, France); Guillouzo, C.; Trincal, G.; Szajnert, M. F. *Eur J Cancer* 14(12): 1341-1347, 1349-1352; 1978.

The principal cytological, growth, and functional changes that appeared in three isolated rat liver epithelial cell lines as they were spontaneously transformed in culture are described, and the posttransformation characteristics were compared with those of LF hepatoma cells. The three lines (FI, FII, and FIII) were isolated from the normal liver of 10-day-old Fischer or Commentary rats; the hepatoma cells were derived from a transplantable tumor. During the first passages, FI, FII, and FIII cells had a flattened epithelial shape and they adhered strongly to the substrate and to their neighbors. FI cells began to show a progressive decrease in adhesion from the 18th to the 30th passage. Gradual overlapping was observed as early as the 13th passage. The protein/-cell ratio in the FI cultures increased by a factor of 3, similar to the hepatoma cultures. The adhesiveness of the FIII cells also decreased progressively, but that of the FII cells did not change. FI cells gave rise to colonies in soft agar and induced tumors 4-9 mo after ip injection of $2-3 \times 10^6$ cells into syngeneic newborn rats; LF cells induced tumors 10 days after injection. FIII cells never produced colonies in soft agar and were not tumorigenic when injected in rats. Pyruvate kinase, aldolase, and glucose-6-phosphate dehydrogenase activity was increased in the FI cells compared to that in FII and FIII cells. The isozyme pattern was the same in all the cell lines studied. Tyrosine aminotransferase (TAT) was increased two to five times by the addition of dexamethasone to the FI cell medium. No TAT induction was observed with FII or FIII. (40 refs)

- 79-1191 Intracapillary Oxyhaemoglobin Saturation in Malignant Tumours with Central or Peripheral Blood Supply and Drainage.** (Eng) Grunewald, W. A. (Inst. Physiology, Univ. Regensburg, D-8400 Regensburg, W. Germany); Manz, R.; Mueller-Klieser, W.; Vaupel, P. *J Physiol (Lond)* 284: 57P-58P; 1978.

A cryophotometric micromethod was used to determine in vivo intracapillary oxyhemoglobin (ic HbO₂) saturation, during normoxia, in sc tissue specimens and in tissue-isolated preparations of the DS rat carcinosarcoma. The former have a peripheral, the latter a central blood supply and drainage. During the same growth stage, ic HbO₂ values were higher in the sc specimens than in the tissue-isolated preparations; ie, there is a heterogeneity of oxygenation within tumors that depends mostly on vascularization patterns. (3 refs)

- 79-1192 "Invasiveness" in Tissue Culture: A Technique for Study of Gliomas.** (Eng) Scott, R. M. (Dept. Neurosurgery, Tufts Univ. Sch. Medicine, New England Medical Center, Boston, MA); Liszczak, T. M.; Kornblith, P. L. *Surg Forum* 29: 531-533; 1978.

The application of an in vitro tissue culture technique with polycarbonate filters for assessing the invasive properties of a glioma was studied using seven human gliomas. The typical grade-1 astrocytoma grew slowly to several layers in thickness on the implanted side of the filter and did not penetrate the filter pores. All glioblastomas rapidly penetrated the filter pores and spread over both sides of the filter. Operating-room explants grew satisfactorily in some cases and could substitute for the standard coverslip cultures when stained directly and mounted flat. This technique was excellent for studying CNS material in tissue culture in that the cells could be seen as they conformed to their substrate, and mobile portions of the cell could be studied as they grew into the filter pores and on the opposite side of the filter. The technique might be used to study the effect of chemotherapeutic agents or x-irradiation on the known penetration characteristics of a particular tumor. (2 refs)

- 79-1193 Effects of Dietary Fats on Mammary Carcinoma in C3H Mice.** (Eng) Bernard, P. (Endocrinologic Pharmacology Res. Lab., Physiology Dept., Southern Illinois Univ., Carbondale, IL, 62901); Pace, M. J.; Gass, G. H. *IRCS Med Sci (Cancer)* 6(11): 489; 1978.

The effects of dietary fat on the occurrence of mammary tumors in female C3H mice with a milk tumor virus (MTV) were studied. At 4 wk of age, the animals were put on Purina Laboratory Chow diets containing 0%, 10%, 20%, or 30% added fat (Mazola oil). The study was run for 53 wk. The incidence of mammary tumors was 21% in the 0% added-fat group, 41% in the 10% added-fat group, 80% in the 20% added-fat group, and 59% in the 30% added-fat group. The increase in tumor incidence over the control value was significant for all added-fat groups. The latent period for tumor formation in all added-fat groups was reduced compared with the control group. Thus, carcinogenesis can occur as a result of a high-fat diet in the presence of MTV without the need for a chemical inducing agent. The critical level of fat needed to produce mammary carcinogenesis is approx 20%. (5 refs)

- 79-1194 Raynaud's Phenomenon. Is It a Paraneoplastic Syndrome (Letter to Editor)?** (Fre) Van der

Meulen, J. (Service de Medecine Interne, Clinique Medicale, Universite de Groningen, Groningen, France); The, T. H.; Wouda, A. A. *Nouv Presse Med* 7(43): 3935; 1978.

Two cases of Raynaud's phenomenon (digital ischemia) preceding a diagnosis of cancer are reported. The first patient, a 49-yr-old woman had Raynaud's disease for 2 yr prior to the diagnosis of a visceral adenocarcinoma. In the second patient, a 60-yr-old man, the ischemia disappeared after excision of an epidermoid tumor of the lung. (6 refs)

79-1195 Palpable Spleens: Ten-Year Follow-Up (Letter to Editor). (Eng) Ebaugh, F. G. (Stanford Univ. Medical Center, Stanford, CA, 94305); McIntyre, O. R. *Ann Intern Med* 90(1): 130-131; 1979.

A 10-yr follow-up study of 58 asymptomatic male college freshmen with palpable spleens showed that they had a significantly higher ($p < 0.05$) frequency of infection and physician office visits, compared with 178 controls. These students had normal hematocrits, reticulocyte counts, blood smears, and heterophil titers at the time the spleen was palpable. There was no evidence of lymphoreticular malignancy in the 58 subjects during the 10-yr period. (2 refs)

79-1196 Safety of Percutaneous Fine-Needle Pancreatic Biopsy: A Porcine Model. (Eng) Coel, M. N. (Radiology Service, Veterans Admin. Hosp., 3350 La Jolla Village Dr., San Diego, CA, 92161); Niwayama, G. *Invest Radiol* 13(6): 547-548; 1978.

Percutaneous fine-needle aspiration biopsy was performed in 15 normal pigs and 10 pigs with experimentally induced pancreatitis with no complications. Pancreatic cells were retrieved in 11/15 and 7/10 pigs, respectively. The results suggest that percutaneous biopsy with cytologic examination for pancreatic carcinoma can be performed in humans preoperatively and, by inference, safely. (13 refs)

79-1197 Ultrasound-Guided Fine-Needle Biopsy in Pancreatic Carcinoma. (Ger) Triller, J. (Institut für diagnostische Radiologie, Universität Bern Inselspital, CH-3010 Bern, Switzerland); Zaunbauer, W.; Fuchs, W. A.; Gretillat, P. A. *ROEFO* 129(6): 695-699; 1978.

The accuracy of fine-needle biopsy (FNB) guided by ultrasound was evaluated in 26 pancreatic carcinoma patients, and the results were correlated with radiological techniques. Needle biopsy of the pancreas proved to be an informative and economical accompanying procedure, since the sonographic demonstration of a pancreatic mass otherwise requires additional radiological and endoscopic investigations. (18 refs)

79-1198 Collagenolytic Activities of Cultured Human Malignant Melanoma Cells. (Eng) Tane, N. (Veterans Admin. Hosp., Univ. Tennessee Center Health Sciences, Memphis, TN); Hashimoto, K.; Kanzaki, T.; Ohyama, H. *J Biochem (Tokyo)* 84(5): 1171-1176; 1978.

Three independent methods (isotope release, disk electrophoresis, and segment long spacing crystallites) demonstrated that the human malignant melanoma cell can produce specific collagenase in a pure culture system. This collagenase was directly extractable from the tumor cells in active form. The high collagenase activity of the early cultures diminished with each successive subculture. (23 refs)

79-1199 A Rapid Micro Scale Method for the Detection of Lysopine and Nopaline Dehydrogenase Activities. (Eng) Otten, L. A. (Dept. Biochemistry, State Univ. Leiden, Wassenaarseweg 64, Leiden, Netherlands); Schilperoort, R. A. *Biochim Biophys Acta* 527(2): 497-500; 1978.

A rapid and sensitive paper chromatographic method, based on phenanthrene-quinone staining, was developed to determine lysopine dehydrogenase and nopaline dehydrogenase activities in crown gall tumor tissues. Enzyme activities as low as 0.2 micromole of octopine or nopaline per hour per gram of tumor tissue can be detected. As little as 5 mg of starting material is necessary. (20 refs)

79-1200 The Influence of Substrate on the Growth of a Human Colon Carcinoma Cell Line (SK-∞-1) and its Production of Carcinoembryonic Antigen (CEA) (Meeting Abstract). (Eng) Pincus, J. H. (Life Sciences Div., SRI International, Menlo Park, CA 94025); Jameson, A. K.; Fischer, M. *Fed Proc* 38(3, Part 2): 1106; 1979. (no refs)

Subject Index

Abdominal Neoplasms

- Adenocarcinoma
 - Raynaud's Disease, 79-1194
- Carcinoma, Basal Cell
 - Case Report, 79-1089
- Raynaud's Disease
 - Case Report, 79-1194

Abnormalities

- 12-*O*-Tetradecanoylphorbol-13-acetate
 - Sea Urchin Embryo, 79-862
- p*-Toluidine, *N*-Isopropyl- α -(2-methylhydrazino)-
 - Teratogenic Effect, Review, 79-607
- Vinblastine
 - Teratogenic Effect, Review, 79-601
- Vincristine
 - Teratogenic Effect, Review, 79-601

Acantholysis

- Carcinoma, Epidermoid
 - Keratoses, 79-1093
 - Neoplasm Recurrence, Local, 79-1093

Acetamide

- Air Pollution
 - Photooxidation Products, 79-772

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-

- Carcinoma, Bronchiolar
 - DNA Repair, 79-746
- Concanavalin A
 - DNA Repair, 79-745
- Escherichia coli*
 - Transformation, Genetic, 79-925
- Fibroblasts
 - DNA Repair, 79-811
- Harman
 - DNA Repair, 79-746
- Lymphocytes
 - DNA Repair, 79-745
- Ultraviolet Rays
 - DNA Repair, 79-924, 79-925, 79-926
 - Transformation, Genetic, 79-925
- Urea, Hydroxy-
 - DNA Repair, 79-745
- Xeroderma Pigmentosum
 - DNA Repair, 79-811, 79-924, 79-926
 - Fibroblasts, 79-924
 - Pyrimidine Dimers, 79-924

Acetamide, *N*-Fluoren-2-yl-

- Barbituric Acid, 5-Ethyl-5-phenyl-
 - DNA, Binding, 79-742
- Benzo(a)pyrene
 - Aryl Hydrocarbon Hydroxylases, 79-884
- Cells, Cultured
 - DNA Repair, 79-741
- Cholanthrene, 3-Methyl-
 - Aryl Hydrocarbon Hydroxylases, 79-744
 - Cytochromes, 79-744
 - DNA, Binding, 79-744
 - DNA Repair, 79-741
- Corn Oil
 - Enzymatic Activity, Liver, 79-739
- Cytochromes
 - DNA, Binding, 79-744

Acetamide, *N*-Fluoren-2-yl- (cont'd)

- Diethylamine, *N*-Nitroso-
 - Ames Test, 79-759
- DNA, Binding
 - Guinea Pig, Rat, 79-744
 - Liver, Rat, 79-742
- DNA Repair
 - Liver, Rat, 79-741
- Dyes
 - Photooxidation, 79-747
- Liver Neoplasms
 - Glucosephosphate Dehydrogenase, 79-743
 - Hyperplasia, 79-743
 - Quinone Reductases, 79-743
- Microsomes, Liver
 - Ames Test, 79-739
- Nucleoproteins
 - Liver, Rat, 79-742
- Oxygen
 - Photooxidation, 79-747
- Retinoic Acid
 - Selenium, 79-740
 - Transferases, 79-740

Thymus Neoplasms

Lymphoma, 79-799

1*H*-Imidazole-1-ethanol, α -(Methoxymethyl)-2-nitro-

Benzo(a)pyrene

Ames Test, 79-884

Carcinoma, Ehrlich Tumor

Micronucleus, 79-798

Radiation, Ionizing

Micronucleus, 79-798

2-Imidazolidinone, 1-(5-Nitro-2-thiazolyl)-

Ames Test

Mutagenic Activity, Review, 79-604

Immunity, Cellular

Barbituric Acid, 5-Ethyl-5-(1-methylbutyl)-2-thio-

Benzimidazole, 2-(4-Thiazolyl)-, 79-1033

Benzimidazole, 2-(4-Thiazolyl)-

Surgery, Operative, 79-1033

Breast Neoplasms

Antigens, Neoplasm, 79-1051

Precancerous Conditions, 79-1051

Down's Syndrome

T-Lymphocytes, 79-1060

Plant Agglutinins, 79-1060

Ethane, 2-Bromo-2-chloro-1,1,1-trifluoro-

Benzimidazole, 2-(4-Thiazolyl)-, 79-1033

Mammary Neoplasms, Experimental

Radiation, Ionizing, 79-1057

Plasmacytoma

Radiation, Ionizing, 79-1057

Virus, Lymphocytic Choriomeningitis

Killer Cells, 79-1036

Virus, Murine Sarcoma

Killer Cells, 79-1036

Virus, Rauscher Murine Leukemia

Killer Cells, 79-1036

Immunoglobulins, Fab

Virus, Murine Sarcoma

Cell Transformation, Neoplastic, 79-1037

Gangliosides, 79-1037

Membrane Proteins, 79-1037

Immunoglobulins, Heavy Chain

Leukemia, Hairy Cell

IgG, 79-1042

Immunoglobulins, Surface

Leukemia, Hairy Cell

Rosette Formation, 79-1042

Leukemia, Lymphocytic

B-Lymphocytes, 79-1041

Immunologic Deficiency Syndromes

T-Lymphocytes

Antibody Formation, Review, 79-626

Immunosuppression

Sarcoma, Kaposi's

Adrenal Cortex Hormones, 79-1143

Azathioprine, 79-1143

Radiation, Ionizing, 79-1143

Surgery, Operative

Benzimidazole, 2-(4-Thiazolyl)-, 79-1033

- Indole-3-acetic Acid, 5-Hydroxy-**
 Aflatoxin B1
 Metabolism, Brain, 79-722
 Aflatoxin B2
 Metabolism, Brain, 79-722
 Aflatoxin G1
 Metabolism, Brain, 79-722
 Aflatoxin G2
 Metabolism, Brain, 79-722
- Infectious Mononucleosis**
 Virus, Epstein-Barr
 Epidemiology, Review, 79-621
- Insulin**
 Carcinoma
 Hyperglycemia, 79-1181
 Diabetes Mellitus
 Streptozotocin, 79-910
- Interferon**
 Down's Syndrome
 Plant Agglutinins, 79-1060
- Intestinal Neoplasms**
 Adenocarcinoma
 Methane, Azoxy-, 79-681
 Adenoma
 Epidemiology, Norway, 79-1144
 Obesity, 79-1144
 Precancerous Conditions, 79-1144
 Alpha 1-Antitrypsin
 Immune Response, 79-1062
 Alpha Globulins
 Immune Response, 79-1062
 Bile Acids and Salts
 Epidemiology, Review, 79-636
 Blood Proteins
 Immune Response, 79-1062
 Clostridium
 Epidemiology, Review, 79-636
 Diagnosis
 Sigmoidoscopy, 79-1140
 Diet
 Epidemiology, Review, 79-637
 Hodgkin's Disease
 Case Report, 79-1119
 Diagnosis, 79-1119
 Hydrazine, 1,1-Dimethyl-
 Dietary Fiber, 79-733
 Methane, Azoxy-
 Colostomy, 79-681
 Disulfide, Bis(diethylthiocarbamoyl)-, 79-681
- Intestinal Polyps**
 Bladder Neoplasms
 Epidemiology, 79-1120
 Colon
 Antigens, Neoplasm, 79-1051
 Leukocyte Adherence Inhibition Test, 79-1051
 Gastrointestinal Neoplasms
 Epidemiology, 79-1120
 Intestine, Large
 Epidemiology, Norway, 79-1144
 Localization
 Epidemiology, 79-1120
 Prostatic Neoplasms
 Epidemiology, 79-1120
- Intestine, Large**
 Intestinal Polyps
 Epidemiology, Norway, 79-1144
- Iridocyclitis**
 Eye Neoplasms
 Neoplasm Metastasis, 79-1083
- Iron**
 Anemia, Aplastic
 Blood Circulation, 79-1066
 Anemia, Hemolytic
 Blood Circulation, 79-1066
 Polycythemia Vera
 Blood Circulation, 79-1066
 Spherocytosis, Hereditary
 Blood Circulation, 79-1066
- Isoantibodies**
 Neoplasms, Experimental
 Antibody-Dependent Cell-Mediated Cytotoxicity
 79-1036
 Virus, Rauscher Murine Leukemia
 Antibody-Dependent Cell-Mediated Cytotoxicity
 79-1036
- Isoenzymes**
 Carcinoma, Bronchiolar
 Hybrid Cells, 79-1106
- Isoflurane**
 see Ether, 1-Chloro-2,2,2-trifluoroethyl Difluoromethyl
- Karyotyping**
 Carcinoma, Bronchiolar
 Hybrid Cells, 79-1106
 Melanoma
 Hybrid Cells, 79-1052
- Kepona**
 Liver Neoplasms
 Carcinogenic Potential, 79-706
 Mouse, Rat, 79-706
 Precancerous Conditions, 79-706
 Ovarian Neoplasms
 Carcinogenic Potential, 79-706
 Precancerous Conditions, 79-706
 Thyroid Neoplasms
 Carcinogenic Potential, 79-706
 Precancerous Conditions, 79-706
- Keratin**
 Stomach Neoplasms
 Urea, Methyl Nitroso-, 79-783
- Keratoacanthoma**
 Anus Neoplasms
 Hydrazine, 1,2-Dimethyl-, 79-732
 Skin Neoplasms
 Benzo(a)pyrene, 10-Methyl-, 79-896
- Keratoses**
 Carcinoma, Epidermoid
 Acantholysis, 79-1093
 Case Report, 79-1093
- 17-Ketosteroids**
 Prostatic Neoplasms
 Metabolism, Rat, 79-916
- Kidney**
 Aflatoxin B1
 Body Burden, Mouse, 79-719

Kidney Diseases

- Bladder Neoplasms
